The Woman's Auxiliary to the San Francisco County Medical Society set a day in February at the Irwin Memorial Blood Bank, 2180 Washington Street, for its members to donate blood for use in local hospitals and to build a reserve in case of enemy attack or other disaster. The Irwin Memorial Blood Bank operates under the direction of the county medical society and as a project the members of the auxiliary entirely staff the following departments: couriers, drivers of the blood bank station wagon, delivery service and Canteen Corps. These volunteers work six days a week from 8 a. m. to 6 p. m. This service has been in operation for the past year. The Telephone Committee, under the direction of Mrs. Frank Hand, contracted the membership to make appointments and furnish all necessary information. Members were asked to give the usual pint of blood needed for adult transfusions or a portion of a pint for infant transfusions, a unique service of the Irwin Memorial Blood Bank.

The regular meeting of the Alameda County auxiliary was held at the Claremont Country Club on February 19 with Mrs. T. Floyd Bell presiding. The third Tuesday of each month the members take over Hospitality House and serve during the day and evening. All food is donated by members. Mrs. Rosner Graham, Hospitality House chairman, has announced that cash contributions during January totaled \$45. The fund necessary to carry on this work is dependent on the voluntary contributions of members.

Indiana

Dr. Carl H. McCaskey, president of the Indiana State Medical Association and Dr. Homer G. Hamer, chairman advisory committee Woman's Auxiliary to the Indiana State Medical Society, were guest speakers at the meeting of the auxiliary in May. A survey of the work done by the members of the Allen and Marion counties in civic and war service was presented. Allen County has a complete cross index file of all doctors, wives in their community and the kind of work done by them.

Oregon

The Woman's Auxiliary to the Oregon State Medical Society has been concentrating mainly on work for the Medical Surgical Relief Committee or America. Instruments and samples of drugs have been collected from doctors' offices. Appeals have been made to housewives for scissors, wooden handled knives and mirrors. In this field the dental auxiliary and through it the Eastern Star has been of great help. When the call came for fishing tackle, anglers' clubs were approached. With their aid a great deal of deep sea tackle has been obtained for use on life rafts. Many of the counties have given money with which to purchase emergency medical kits.

A streamlined annual meeting of the auxiliary will be held when the medical society meets on September 4-5 in Portland. Two new auxiliaries have been organized in Baker County and in Ontario County.

Pennsylvania

The Philadelphia auxiliary held a bazaar recently in the County Medical Society Building, Philadelphia, from which more than \$800 was netted as a result of the efforts of the chairman of welfare, Mrs. John B. Lowne, and her committee. The executive board with the president, Mrs. George C. Yeager, in the chair, voted to give \$500 to the Aid Association of the Philadelphia County Medical Society. The speaker was the Rev. W. Sherman Skinner, pastor of the First Presbyterian Church in Germantown.

Mrs. Anna de Planter Bowes, chief of the division of nutrition, state department of health, recently addressed the Cambria auxiliary.

The Huntingdon auxiliary recently sponsored its first Health Day. Mrs. Anna de Planter Bowes spoke on "Food Is Power." About 250 people were in attendance.

Texas

Kerr-Kendall-Gillespie-Bandera counties auxiliary held a meeting recently in Fredericksburg. Members reported a total of one hundred and eight hours on Red Cross work during December and the making of 368 surgical dressings. The auxiliary voted a donation of \$10 to the Memorial Fund and \$5 each to the state student funds for 1943. Mrs. Walter Minsch, reporting on the sale of tuberculosis seals in Kerr County, which project was sponsored by the auxiliary, announced that \$765 had been received to date. The auxiliary voted to buy a \$25 War Bond to be placed in the savings with other bonds already owned by the auxiliary.

Virginia

In spite of the difficulty in securing linens the annual hospital linen shower of the Petersburg auxiliary netted donations of 116 sheets, 17 spreads, 73 bath towels, 59 face towels, 61 pillow slips, 39 wash cloths and 1 quilted pad. In addition \$39.50 was given in cash with which necessary linens will be bought.

Changes have been made in the officer personnel of the auxiliary because of the fact that some of the officers have left the city with their husbands who are in the armed forces. Officers now are president, Mrs. H. M. Snead, president-elect, Mrs. J. E. Hamner, vice president, Mrs. C. S. Dodd, treasurer, Mrs. Meade Edmunds, recording secretary, Mrs. W. B. McIlwaine and corresponding secretary, Mrs. C. T. Jones.

Wisconsin

Two hundred members and guests attended the meeting of the Woman's Auxiliary to the Medical Society of Milwaukee County on Lincoln's Birthday. Among the guests were members of the Washington, Ozaukee and Waubesa county medical auxiliaries and members of the Milwaukee dental auxiliary. The guest speaker was Commander Bart W. Hogan, Senior Medical Officer aboard the aircraft carrier *U.S.S. Memphis*. Members of the auxiliary who are nurses have been asked to fill out questionnaires which will be used in a survey of nursing resources in Wisconsin. Mrs. Edith M. Partridge, chair executive secretary of the Wisconsin State Nurses' Association, has charge of this survey.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

ARKANSAS

New Director of Crippled Children—Dr Vida H Gordon, director of the Sanilac County (Mich) Health Department since June 1941, has been appointed director of crippled children activities in Arkansas with headquarters in Little Rock. Dr Gordon was recently elected president of the Sanilac County Medical Society.

CALIFORNIA

Personal—Dr Harold Shyrook, assistant professor of anatomy (microscopic), will be acting dean of the College of Medical Evangelists, Loma Linda-Los Angeles, until the recently appointed dean, Dr Newton G Evans, is able to move to Loma Linda and to accept full administrative activities.

California's Health—With the July 15 issue the *Weekly Bulletin* of the state department of public health became *California's Health*, which hereafter will be issued every other week instead of every week. The *Weekly Bulletin* has been published since Feb 18, 1922. Prior to that date the departmental publication was a monthly bulletin, which was first published in June 1905.

DISTRICT OF COLUMBIA

Department of State Visitors—The following have recently arrived in Washington as the guests of the Department of State. Madame Jacqueline Wiener-Silvera, leader in child welfare from Haiti and founder and president of the League for the Protection of Children there, Dr Xavier da Silveira, head of the Surgical Clinic in the Polyclinic at Rio de Janeiro, who arrived for a tour of the United States under a similar invitation, Dr Lauro Cruz Goyenola, Uruguayan specialist in rural medicine, who will make a special study for his government on popular health education and is a former president of the Medical Society of Eastern Uruguay and at present an officer in the clinical surgical service of the national hospital system of Uruguay, and Dr Heitor P Froes, chairman of tropical diseases on the federal faculty of medicine at Bahia.

Personal—John B Parker, Ph D, since 1910 a member of the faculty of the Catholic University of America, Washington, has been made professor emeritus of biology. Charles L Newcomb has been named acting executive secretary of the Tuberculosis Association of the District of Columbia, succeeding Harold H Lund. Brig Gen Fred W Rankin, Army Medical Corps, received the honorary degree of doctor of science at the commencement exercises of Northwestern University, Chicago, on June 16. Dr Joseph T Roberts, formerly assistant professor of internal medicine and anatomy and director of the experimental laboratory department, University of Texas School of Medicine, Galveston, has been appointed adjunct clinical professor of medicine on the faculties of the schools of medicine of Georgetown University and George Washington University, Washington, he is also chief medical officer at Gallinger Municipal Hospital.

ILLINOIS

Personal—Dr Amzi P Kannapel has been appointed editor of the *Peoria Medical News* to succeed Dr Enil Z Levitin, who held the office for almost fifteen years.

Chicago

Luncheon in Honor of Dr Lebedenko—The Russian War Relief, Inc, announces a luncheon in honor of Dr V V Lebedenko, professor of surgery, First Moscow Medical Institute, and representative of the Russian Red Cross and Red Crescent, at the Palmer House on August 17. Dr Lebedenko will give an address on "Soviet War Medicine."

Bevan Bequest to Surgical Fund—The will of the late Dr Arthur D Bevan provides for a bequest of \$5,000 to the Trustees of Rush Medical College. The amount is to be added to the Thomson-Bevan Surgical Fellowship Fund, established in 1914 by gifts of Mr A D Thomson and Dr Bevan. The annual income from the fund provides a fellowship for a resident surgeon or head surgeon at Presbyterian Hospital. On the death of the primary beneficiaries of the will, \$25,000 will go

to the Lake Forest Hospital, Lake Forest, Ill, as a surgical endowment and the residue will go to the Presbyterian Hospital to establish a perpetual endowment.

Society Urges Complete Filtration for Lake Water—At a special meeting of the Council of the Chicago Medical Society on July 20 approval was given to a report recommending that complete filtration of Lake Michigan should be carried out. The report, submitted by an advisory committee headed by Dr Robert A Black, stated that "the pollution of the water at the south end of Lake Michigan at the intakes of the 68th Street and Dunne cribs is a potential danger to the health of 1,400,000 citizens on the south side of Chicago. Chlorination alone will not make it safe during periods of high pollution. The only adequate protection of Chicago water is filtration followed by chlorination." In a Washington conference Abel Wolman, D E, chief consultant for the water division of WPB, stated that in his opinion the amount of impurities in Chicago water at present does not require any immediate action. Dr Herman N Bundesen, president of the Chicago Board of Health, said that the increase in bacteria count in the first eight days of July was alarming. Dr Bundesen submitted figures showing that the impurities during this period were nearly three times as great as in June, it was reported.

MARYLAND

Personal—Dr Theodore R Shrop, Cumberland, has been appointed a deputy state and county health officer of Garrett County, succeeding Dr Henry Rolfe DePuy, Oakland, who resigned on Sept 1, 1941. Dr Henry N Harkins, a member of the staff of Henry Ford Hospital, Detroit, on July 1 became associate professor of surgery at Johns Hopkins University School of Medicine, Baltimore.

Yellow Fever Volunteer Dies—Clyde L West, a trial magistrate in Calvert County and one of the group of volunteers who was infected by mosquitoes in the experimental inoculation conducted in Cuba during the Spanish American War by Major Walter Reed, M C, U S Army, died on July 16 of heart disease, aged 66. According to an Associated Press dispatch from North Beach, Mr West was taken sick with yellow fever on Feb 3, 1901 and discharged from the service on July 10, 1902 at Fort Meyer, Va. He had been inoculated at Camp Lazear, Cuba.

MISSOURI

Annual Fall Clinical Conference—The Kansas City Southwest Clinical Society will hold its annual fall clinical conference, October 4-6. The conference will be made up of round table discussions, lectures, demonstrations and refresher courses in medicine and surgery and the specialties. The preliminary program includes the following speakers: Drs Frank H Lahey, Boston, Harrison F Flippin, Philadelphia, William F Mengert, Iowa City, Edward H Ryncarson, Rochester, Minn, Tom D Spies, Birmingham, Ala, Cyrus C Sturgis, Ann Arbor, Mich, and Paul D White, Boston.

Health Forum—The Jackson County Health Forum, sponsored by the auxiliaries of the accredited hospitals of Jackson County, will begin its 1943-1944 season on September 15 with a talk by Dr French K Hansel, St Louis, on "Hay Fever and Asthma." Others in the series, which is open to the public, will be

Dr Fred M Smith, Iowa City, Some of the Things That a Layman Should Know About His Heart October 20

Lon W Morrey D D S Chicago Your Teeth and Their Importance to General Health November 17

Dr William W Bauer director of the Bureau of Health Education American Medical Association, Chicago Eat What You Want, January 19

Dr Walter Freeman, Washington, D C, War—Is Good for the Nerves But February 16

Dr Ralph Pemberton Philadelphia Rheumatism Arthritis and Related Diseases March 16

Dr Morris Fishbein Editor of THE JOURNAL, New Knowledge of Cancer April 19

NEW JERSEY

Personal—Rutgers University, New Brunswick recently conferred the honorary degree of doctor of science on Dr Wells P Eagleton, Newark, for his many attainments during the many years of his practice as a physician. William O Frohman, recently elected director of the American Home Products Corporation, Jersey City, has been appointed special technical consultant to the corporation and its subsidiaries. He will concentrate on research and development work in connection with new products to be introduced when the war ends. Mr Frohman resigned as president and general manager of S I A Corporation, a subsidiary of American Home Products.

accept the new position—Dr Stephen A. Douglass Paterson, has been elected president of the New Jersey Tuberculosis League, Newark, succeeding Dr Elvira D. Abell, Morristown.

NEW MEXICO

State Medical Election—Dr Carl H. Gellenthien Valora, was chosen president elect of the New Mexico Medical Society at its recent meeting, and Dr Joseph E. J. Harris, Albuquerque, was installed as president. Dr Leo B. Colman, Albuquerque, is the secretary-treasurer. The next session will be in Albuquerque sometime in May.

NEW YORK

Examination for Assistant District Health Officer—The state department of civil service will conduct an examination for assistant district health officer of the New York State Department of Health on September 1. The salary range of the position is \$4,000 to \$5,000. Applications and tests must be submitted to the department of civil service by August 24. Accepted candidates will be notified when and where to appear for examination. If an applicant is rejected, notice will be sent and the fee will be refunded after the examination has been held. Candidates must be United States citizens who have been legal residents of New York State for not less than one year. Additional information may be obtained from the department of civil service at Albany.

Dr Parnall Placed in Charge of Hospital Survey—Dr Christopher G. Parnall, medical director of the Rochester General Hospital, Rochester, has been granted a six months leave of absence to serve as director of a survey of the twenty-six state operated mental hospitals. The survey is a part of the investigation recently inaugurated under the Morland Act (THE JOURNAL, June 12, p. 456) and will be divided into six main fields of study: studies and inquiries into admission and discharge procedures, personnel, professional care of patients, physical plans in the hospital structures, collection of funds for patient care and the administrative setup of the department. Archie O. Dawson, lawyer, chairman of the five members comprising the Morland act commission, states in an announcement to the press that Dr Parnall will be assisted by a staff of experts in the field of hospital administration, nursing care, social service, dietetics, psychiatric work and the medical care of patients.

New York City

Chinese Blood Bank—The Chinese Blood Bank opened at 134 Nassau Street in June, is the first blood bank in the world entirely manned by Chinese doctors, nurses and technicians to prepare plasma for the armies of China. Dr J. Heng Liu, medical adviser to the Chinese division of the Lend Lease Administration, was the first donor. Eighty-three donations were received during the first week of operation, nearly all of which were from Chinese. The staff is headed by Dr Chien-lung Yi, who has studied the technique of plasma drying with Dr John Scudder at Presbyterian Hospital and Sloane Hospital for Women and with Dr Max Strumia at Bryn Mawr Hospital, Bryn Mawr, Pa. Dr Arthur Liu is clinical director and Mrs. Jean Chum Liu is the nurse in charge. Louis de Fott oversees the mechanical equipment, which includes a refrigerated cabinet and a Strumia dehydration unit with a shell-freezing bath. Because malaria is endemic in China, there is also a Seitz filter which, by sterilizing blood plasma, can eliminate malaria micro-organisms. Preparations for the opening of the blood bank had been going on for more than a year under the supervision of Dr Scudder, director of the blood bank at the Presbyterian Hospital. Special training was provided so that the Chinese personnel will be able to take the machinery back to China after its trial run in New York. There they will set up the blood bank and pass on their knowledge to others so that more blood banks may be operated as needed by the Chinese army. (THE JOURNAL, June 26, p. 630).

OHIO

Reid Memorial Fund—A public campaign to raise at least \$500,000 to be donated to the University of Cincinnati College of Medicine as a fund dedicated to the memory of Dr. Mont R. Reid was launched on July 12 under the auspices of a local committee of sponsors. The fund is to be used to supplement the regular budget of the college of medicine and is intended to honor the memory of a great citizen to advance the cause of medical science and teaching and to promote the health of our community. An annual deficit varying from \$18,000 to \$25,000 was usually met through the personal efforts of Dr. Reid and it is believed that a fund to insure the activities of the department will be a suitable memorial in his honor.

Physician Honored by Academy of Medicine—At a recent meeting of the Academy of Medicine of Cleveland, Dr. Howard Dittick, for many years a member or chairman of the publications committee, was presented with the academy's distinguished service award for 1943. The award consisted of a silver plate and went to Dr. Dittick in recognition of his service to the academy over a long period of time. He has been on the membership committee, chairman of the clinical pathologic section and program committee and director and chairman of the publication committee and editor of the *Bulletin of the Academy of Medicine of Cleveland* almost uninterruptedly since 1934. He has been a trustee of the Cleveland Medical Library since 1927, serving for a time as director of membership and director of programs. In 1928 he became curator and in 1935 director of the Museum of Historical and Cultural Medicine.

PENNSYLVANIA

Position Available as Venereal Control Officer—The Merit System of the state department of health announces an examination to fill the position of chief of the venereal disease division. Applications, which must be received from the Merit System Office, 207 Blackstone Building, Harrisburg, must be postmarked before August 20. Requirements include graduation from an approved school, licensure or eligibility for licensure in Pennsylvania, one year's graduate training and experience in venereal disease work and completion of a year's acceptable course in public health prior to appointment or within three years after assuming office. The examination will consist of a rating of training and experience and of an oral examination.

TEXAS

Members of State Medical Board—Dr. Marion M. Brown, Mexia, was recently elected president of the Texas State Board of Medical Examiners, Dr. Everett W. Wilson, San Antonio, vice president and Dr. Thomas J. Crowe, Dallas, re-elected secretary-treasurer. Miss Marion Wood, Dallas, is the executive secretary. Other new members of the board are Drs. William E. Watt, Austin; Seeley T. Pulliam, Houston, and Gilliam M. Stephenson, Cisco.

Baylor Opens in New Quarters in Houston—Baylor University College of Medicine now occupies quarters in Houston, the equipment from Dallas having been installed in a large building formerly used as a Sears Roebuck retail store. Houston physicians are cooperating in the teaching facilities and clinical accommodations are available through the Jefferson Davis Hospital, a city-county unit of 500 beds and the Hermann Hospital of 240 beds. The new school has eighty-four students in its freshman class. The upper classes are smaller. Baylor has Army and Navy contracts, and all of the Navy students who were in Dallas have been ordered to the Houston school. Recent appointments to the Baylor faculty include that of Dr. James A. Greene, associate professor of theory and practice of medicine, State University of Iowa College of Medicine, Iowa City, who has been named professor and chairman of the department of medicine and dean of the clinical faculties. Baylor University College of Medicine was first organized in Dallas in 1900 as the University of Dallas Medical Department. In 1903, assuming its present title, the school became the medical department of Baylor University at Waco. In 1904 it acquired the charter of the Dallas Medical College and in 1918 absorbed the Fort Worth School of Medicine. Dr. Walter H. Moursund, Sr. is dean of Baylor.

WISCONSIN

Lectures on Medicomoral Problems—Dr. Ervin T. Huber, St. Louis University School of Medicine, gave the first in an annual series of lectures on medicomoral problems at Marquette University School of Medicine, Milwaukee, recently. The lecture series, named after the Jesuit medical missionary Rene Goupil, is intended to provide physicians with an insight into moral and religious problems in practice.

Twenty-Five Years of Service—Gold keys and certificates for twenty-five or more years of service were recently presented to the faculty of Marquette University School of Medicine, Milwaukee. Dr. Eben J. Carey, dean of the medical school, was toastmaster. Four of those honored had served the medical school since its organization in 1912. They are: Henry L. Banzhaf, DDS, and Drs. Matthew N. Federick, Chester A. Kissinger and Simpson M. Markson. Other faculty members honored included Drs. Edward F. Barta, Charles J. Coffey, Charles Fidler, Harry J. Heeb, Samuel G. Higgins, Joseph Lettenberger, Francis B. McMahon, Herbert W. Power, Louis F. Ruschhaupt, James C. Sargent, Frederick A. Stratton and Joseph C. Bock, PhD. In addition to faculty members, several staff members of the school were also honored.

GENERAL

Obstetricians Postpone Meeting—The American Association of Obstetricians, Gynecologists and Abdominal Surgeons has voted to postpone the annual meeting, which was to have been held at The Homestead, Hot Springs, Va., September 9-11.

More Fellowships in Health Education—Fellowships in health education for training at Yale University, the University of Michigan and the University of North Carolina have been announced by the United States Public Health Service. These fellowships have been made possible by the W. K. Kellogg Foundation, Battle Creek, Mich., through a grant to the United States Public Health Service. Twenty-six young women are now enrolled in the School of Public Health at the University of North Carolina working for their master's degree in public health. The additional fellowships will be awarded for the fall term beginning this September. Basic requirements for application include a B.A. or B.S. degree from an accredited university with major emphasis in the medical and social sciences and education. The successful completion of a year's work leads to a master's degree in public health. Interested and qualified persons must submit their applications to the Surgeon General of the U. S. Public Health Service not later than September 4. Announcement of the successful candidates will be made on September 7.

U. S. Pharmacopeia Sales Increase—A report on the financial status of the U. S. Pharmacopoeial Convention for the year ended April 30 indicates that the increase in income over the expense of the year is primarily found in the sale of pharmacopeias, represented principally by the U. S. Pharmacopeia XII sales. It is interesting to note that volume sales of U. S. P. XII almost parallel those of U. S. P. XI, U. S. P. XII sales leading, however, at all periods to date. It is obvious that the increased income during this initial period represents a reserve for the maintenance of the revision program for the coming years, a program which will finally bring forth another edition of the Pharmacopeia, new, up to date and in keeping with the times. The increased publication and sales expenses naturally represent, for the most part, costs of printing and binding for the U. S. P. XII to date. A portion of the initial printing is yet to be bound. Administration, convention, revision and research costs have all shown a decided decrease for the year in practically every phase of expense. The report states that the total income was \$201,065.79 and the expenses \$62,014.87, leaving an excess of income over expense of \$139,050.92.

Leslie Dana Medal Awarded to Dr. Lancaster—Dr. Walter B. Lancaster, now in private practice in Boston, has been awarded the Leslie Dana Gold Medal, awarded annually for outstanding achievements in the prevention of blindness and the conservation of vision. Dr. Lancaster was chosen for the honor by the St. Louis Society for the Blind, through which the medal is offered by Mr. Leslie Dana of St. Louis. The award is given on the recommendation of the Association for Research in Ophthalmology. To commemorate his eightieth birthday, which he recently observed, the *American Journal of Ophthalmology* for May was designated the Lancaster Testimonial Issue. He was chairman of the Section on Ophthalmology of the American Medical Association in 1928. He was president three times of the New England Ophthalmological Society, serving in a similar capacity in 1924 with the American Academy of Ophthalmology and Otolaryngology and in 1935 with the American Ophthalmological Society. Recently he concluded two years as chief of staff of the Dartmouth Eye Institute and ophthalmic surgeon of the Mary Hitchcock Memorial Hospital, Hanover, N. H. (*THE JOURNAL* June 5, p. 387).

Automobile Deaths Decrease—Deaths resulting from motor vehicle accidents throughout the country in the first six months of 1943 totaled 10,030, a reduction of 41 per cent from the total of the comparative period in 1941 before the outbreak of the war and 32 per cent in 1942, according to the National Safety Council. Public cooperation is held largely responsible for the decrease even though most of it may be attributed to wartime restrictions on speed and mileage. All but one of the thirty-eight states whose motor vehicle death figures were available for the first six months of 1943 showed drops from 1942 levels. Every one showed a reduction from 1941. The 1941-1943 changes for the first half of both years ranged from a 77 per cent drop in Wyoming to almost no change. South Carolina's 67 per cent reduction from 1941 was the second largest drop, and Indiana and Georgia were next with 56 per cent reductions. North Atlantic and South Atlantic regions have not shown the drops in fatalities anticipated because of the drastic curtailment of motor vehicle travel in those areas. Other regions have shown larger decreases in fatalities. A total of 337 cities of 10,000 or more population, whose motor vehicle

traffic death figures for the first half of the year were available, showed an average fatality reduction of 19 per cent as compared with the first half of 1942. According to the safety council, this is substantially under the nationwide drop of 32 per cent, so the largest traffic fatality reduction evidently is continuing to come from rural areas.

Government Services

Dr. Vonderlehr Named Director in Puerto Rico and Virgin Islands

Dr. Raymond A. Vonderlehr has been appointed director of district number 6 of the U. S. Public Health Service covering Puerto Rico and the Virgin Islands. Dr. Vonderlehr recently completed eight years' duty as assistant surgeon general in charge of the division of venereal diseases. He has been identified since 1925 with the U. S. Public Health Service. He was first assigned to the U. S. Marine Hospital at Boston in charge of the venereal disease wards. The following year he was stationed at Ellis Island, New York. From 1927 to 1930 Dr. Vonderlehr was assigned to foreign duty in the Irish Free State, England, Germany and Belgium. During this period he furthered his specialty by postgraduate study at syphilis clinics in Germany, England, Scotland and Wales. In 1931, shortly after his return to the United States, he was assigned to the division of venereal diseases and continued in that work to the present time.

New Head of Bureau of Animal Industry

Arthur W. Miller, D.V.S., since 1927 assistant chief of the Bureau of Animal Industry, U. S. Department of Agriculture, Washington, has been appointed in charge of the bureau to succeed John B. Mohler, D.V.M., who retired on July 31 after holding the position for twenty-six years. Dr. Mohler, who received his degree of doctor of veterinary medicine from the University of Pennsylvania in 1896, has been associated with the Bureau of Animal Industry in various capacities since 1897. He has been awarded many honorary degrees and is a member of numerous scientific societies, serving as president of the American Veterinary Medical Association in 1913, U. S. Livestock Sanitary Association in 1925 and of the International Veterinary Congress in 1934. In 1940 he was awarded the twelfth International Veterinary Congress prize and in 1941 was the Kober lecturer. Dr. Miller, who received his degree at the Kansas City Veterinary College in 1901, has been connected with the Bureau of Animal Industry since 1907.

Guard-Attendants and Medical Technical Assistants Needed

The U. S. Civil Service Commission has announced an examination to secure medical guard-attendants and medical technical assistants for the U. S. Public Health Service. Applicants for medical guard-attendant positions, which pay \$1,970 (counting overtime compensation) a year, must be registered graduate nurses or have had at least three years' service in the medical corps of the Army or Navy or have had eighteen months' service as hospital attendant-guards in any one of the Department of Justice penal or correctional institutions, in the Medical Center for Federal Prisoners, Springfield, Mo., or in the U. S. Public Health Service Hospital at Lexington, Ky., or at Fort Worth, Texas. It is desirable that applicants should have had satisfactory experience as guards in penal or correctional institutions, as soldiers, sailors or marines, or as hospital or asylum attendants. Applicants for the technical assistant positions, which pay \$2,433 a year (counting overtime compensation), must possess the qualifications for medical guard-attendant and in addition must have had one year of training or experience in one of the following options: clinical laboratory technique, pharmacy or x-ray laboratory technique. Applicants must have reached their twenty-first birthday. There is no maximum age limit. No written test is required. Persons now in their highest skills in war work should not apply. Appointments in federal positions are made in accordance with War Relocation Commission policies and employment stabilization plan. Persons who received eligible ratings under the examination announced for these positions in July 1941 need not apply again. Further information and application forms may be obtained at first or second class post offices, at U. S. regional offices and the commission in Washington, D. C.

Struggle Over Government Scheme for State Medical Service

It has been indicated in previous letters to *THE JOURNAL* that the main subject of contention between the medical profession and the government in the Beveridge scheme will be control by lay bodies. A controversy on the point is now being waged in the *Times*. In a joint letter a number of public men point out that local authorities are the backbone not only of our democratic machine but also of our health services. They are responsible for maternity and child welfare, nursery, the school medical and the tuberculosis services and the provision on an extending scale of clinics for various specialized services. They play a major part in providing general and special hospitals and almost entirely provide the mental hospital. It is therefore argued that it would be disastrous if they had no function in the forthcoming development of the nation's health services and as a result many of their other functions were crippled.

To this Dr G. C. Anderson, secretary of the British Medical Association, replied that the main issue has been avoided. It is whether existing local health authorities are satisfactory bodies for administering a comprehensive including a personal health service. Does the layman want the doctor-patient relation to be invaded by the state and the doctor to serve the state rather than the patient? Does he desire that a free profession should be converted into a salaried branch of local government? Doctors are convinced that local government is ill equipped to bear the responsibility of a vast and comprehensive personal health service. Local government areas do not coincide with natural hospital areas and the mere grouping of local authorities will not put this right. There should be a comprehensive health administration locally as well as centrally. The existing proposals only add yet another local authority to the present jigsaw administration.

The caliber of local government membership varies greatly in different areas. Those elected by the people all too often on a political ticket, are not necessarily equipped to administer a service which includes personal health. Doctors agree with the contention that the users of a public service should have free access to those responsible for its general management. But they say that it is in the public interest that they and the voluntary hospitals should be adequately represented on local representative bodies as well as constituting an advisory machinery.

Fall in the Death Rate Due to Use of Sulfonamides

The improvement in our vital statistics during the war has been previously described in *THE JOURNAL*. In the *Lancet* May 29, page 672, Dr Percy Stocks, medical statistician in the General Register Office, states that the vital statistics of England and Wales in 1942 would have been remarkable even in peacetime. The standardized death rate of civilian females was 6.8 per thousand living, of which 0.08 was due to enemy action and the selective effect of recruitment on the civilian population. The previous lowest rate was 7.43 in 1939. Thus the third year of the war had a rate 9 per cent better than that of any peace year. Civilian males gave a standardized rate of 9.54, which was 0.18 below the previous record of 1939, despite considerable inflation of the rate by selective recruitment.

Comparing 1942 female death rates with those of 1939 there is found a 3 per cent fall in childhood, increasing on passing up the years to 15 per cent in old age. Some important influence tending to reduce mortality, Dr Stocks thinks, must have operated first on the younger ages and then spread up the scale in the period 1939-1942. Natural or social causes can scarcely have been responsible, but sulfonamide therapy, applied, like most remedies in the first instance to younger patients while the drugs were in short supply, and later to older people also, as they became more plentiful, provides a possible explanation. Much of the mortality of childhood, and indeed of all ages arises from the infective complications of diseases which otherwise are not highly fatal.

If this is the true explanation, the diseases treated by sulfonamide compounds ought to account for most of the decline. This has been found. Comparing 1942 with 1938, the deaths from the following diseases diminished in the percentages given: scarlet fever 33, whooping cough 76, measles 30, gonococcal infection 75, erysipelas 41, lobar pneumonia 61, other pneumonia 84, septicemia and pyemia 80, mouth and throat diseases 61, ear and mastoid diseases 72, appendicitis 67, puerperal sepsis 77, diseases of the skin and subcutaneous tissues 72. Taking together all the sulfonamide groups, the deaths fell from 41,335 in 1938 to 30,482 in 1942. Dr Stocks concludes that though alternative explanations might be advanced, the lives saved by sulfonamides in 1942 ran well into five figures, neutralizing the increase in deaths since 1938 due to the rising population of old people and sensibly reducing the standardized death rate.

The Danger of Overspecialization

The triennial Hunterian Oration at the Royal College of Surgeons was delivered by Mr Victor Bonney, consulting obstetric and gynecologic surgeon to the Middlesex Hospital. Mr Bonney took for his subject "The Forces Behind Specialism in Surgery." He traced the beginning of specialism to the time when primitive man must have found that better clubs and clothes would be produced if one man made the one and another man the other. Passing from the general to surgery in particular there later arose the medicine man, who combined the roles of doctor, priest and wizard. The separation of surgery from medicine became distinct in England in 1308, when the Company of Barber Surgeons is first mentioned. Not till 1744 was this association dissolved and the surgeons became a separate company. Now surgery had twelve separate departments in which he included obstetrics and gynecology.

The need for and the advantages of this subdivision were manifest but a master of one specialty himself he gave a warning against overspecialization which produced a narrow outlook. To guard against this every aspirant to surgical specialism should undergo adequate training in surgery in general. Since all parts of our art overlap nothing would be so harmful as its division into a number of watertight compartments. Every one working in a special department should have rooted in his mind that his prime allegiance is owed to surgery as a whole and not to the subsidiary shrine where his immediate service lies. He should be competent to deal with every condition with which he may be confronted. Thus the gynecologic surgeon should be familiar with the surgery of the bladder, the rectum and the abdominal contents generally and should perform such operations as the occasion demands. If he cannot occasions will certainly arise when his limitation will be harmful and even disastrous to the patient.

The Threatened Decrease of Population

The threatened decrease in our population due to the fall of the birth rate is causing much concern. In the House of Lords Earl de la Warr said that in 1939 109 women of child bearing age were producing only 75 girls to take their place. This figure compared with 155 in 1880 and 115 in 1911.

Assuming no further decline on the present figure, our population would fall to 34 million in 1980. The gravity of the position was masked by a decrease in the mortality of the aged, which meant nothing as regards reproduction. Not only would we be fewer in 1980 but the age composition of our population would be different. Nearly a fourth of us would be old age pensioners, those over 60 having risen from 7.5 per cent in 1880 to 11.5 in 1930 and 22.5 in 1980, with a corresponding smaller proportion of young people to support the old. A steady decrease of population with an ever growing proportion of old to young was the way to extinction as a nation.

In the debate which followed it was stated that the cause of the fall in the birth rate was mainly economic and that the profound effects of the practice of contraception were not realized. Lord Dawson (consulting physician to the London Hospital) said that the churches had made a fundamental mistake in condemning contraception as such. They should have said that contraception should be rightly used and that adequate parentage was a duty of young people. Family allowances were sound and would be a great help. There should also be better housing. With these and suitable propaganda the idea of larger families could be engendered. For the government the duke of Devonshire said that the whole question bristled with difficulties. He was one of those who viewed the position with alarm. The birth rate of 35.1 per thousand in 1855 had fallen to 15.3 in 1935. Our population doubled in the nineteenth century. The decline of population was now threatened in nearly all northwestern Europe except Russia. The governments of Italy and Germany made considerable efforts to stimulate the birth rate. In Italy these had comparatively little effect, but in Germany there was substantial, though not enormous, success. By all kinds of devices they had raised the birth rate to about half what it was fifty years ago. With the object of meeting a real need, the minister of health proposed to publish a document in which the statistical outlook would be set out and discussed in a balanced manner.

Anglo-Soviet Medical Cooperation

Prof. S. A. Sarkisov, representing the executive committee of the Soviet Red Cross and Red Crescent societies, has arrived here to establish contact with the British Red Cross and British medical scientists and to develop mutual exchange of experience in the treatment of sick and wounded soldiers and in assistance to the civil population who have suffered as a result of the war.

BRAZIL

June 30, 1943

Brazilian Physicians Offer an Airplane to the Army

In March 1942 the medical associations of the city of Rio de Janeiro decided to open among their members the subscription for the sum necessary to buy a military airplane to be offered to the Brazilian army. These associations are the National Academy of Medicine, the Society of Medicine and Surgery of Rio de Janeiro, the Brazilian College of Surgeons, the Brazilian Medical Syndicate, the Society of Neurology, Psychiatry and Legal Medicine, the Society of Dermatology, the Society of Pediatrics, the Society of Biology, the Society of Obstetrics and Gynecology, the Society of Ophthalmology, the Society of Gastroenterology and Nutrition, the Society of Tuberculosis, the Society of Traumatology and Orthopedics, the Society of Mental Hygiene, the Society of Traumatology and the St. Lucas Medical Society. The acting committee included Drs. C. de Sant'Ana, Aenor E. Lins and Oscar Alves. The total sum has almost been raised and the committee has

decided that the airplane shall be fitted to serve as a medical transport and will be named after a great army physician of the past, Dr. Severiano de Rezende.

New University School of Nursing

The first school of nursing of high standard in Brazil, the Ana Nery School of Nursing, founded in the Rio de Janeiro Health Department by a group of American registered nurses in 1923, was transferred to the University of Rio de Janeiro in 1937. A few months ago the arrival of Miss Mary E. Tennant, staff member of the International Health Board of the Rockefeller Foundation in São Paulo, was reported (*THE JOURNAL*, May 2, 1942, p. 96) to study local conditions in order to start a school of nursing at the university in cooperation with the foundation. This plan will be put into effect immediately except that it will not be the foundation that will cooperate with the São Paulo University but the Special Service of Public Health, the institution organized by the coordinator of Inter-American affairs to cooperate financially and technically with the Brazilian government in the tremendous work of sanitation of the Amazon basin (rubber), of the Rio Doce valley (iron deposits) and several other tasks. On the university grounds a new building will be erected to accommodate the school and the nurses' residence. The Special Service of Public Health will finance the construction of the building, and the state of São Paulo will equip the school and the residence. The building will cost \$300,000, and the equipment \$100,000. Everything in the new school will be the best and the newest American brand.

Brazilian-American Committee of Pediatrics

A meeting of Brazilian specialists in pediatrics was held recently in Rio de Janeiro to choose the Brazilian physicians who will represent this country in a Brazilian-American Committee of Pediatrics to be established in the near future. Dr. J. Martinho da Rocha, professor of pediatrics at the University of Rio de Janeiro, Dr. Mario Olyntho, professor of child hygiene of the course of public health of the Oswaldo Cruz Institute, and Drs. Adamastor Barbosa, Leonel Gonzaga and Cesar Pernetta were chosen for the committee. All these specialists have served in succession as presidents of the Brazilian Society of Pediatrics during recent years.

Dr. Bernardo A. Houssay

Dr. Bernardo A. Houssay, professor of physiology of the University of Buenos Aires, Argentina, arrived at Rio de Janeiro, June 28, on invitation of the University of Rio de Janeiro, of the Committee of Intellectual Cooperation, of the Brazilian Academy of Science and of the Biologic Society of Brazil to deliver several lectures in his specialty. On June 29 Dr. Houssay was received by the faculty of the Medical School of the University of Rio de Janeiro. Dr. Moysio de Castro, professor emeritus of medicine, presided at the meeting and welcomed Dr. Houssay. Immediately afterward Dr. Houssay delivered his lecture on the subject of "The Scientific Investigation." On July 6 and 8, at the Brazilian Academy of Sciences and at the National Academy of Medicine, Dr. Houssay lectured respectively on "Thyroid and Diabetes" and on "Regulation of the Internal Secretion of the Pancreas."

Course in Hospital Administration

Dr. Felix Lamela, executive secretary of the Inter American Hospital Association, founded in September 1911 at the meeting of the American Hospital Association, is now in Rio de Janeiro, where he is organizing, in collaboration with Brazilian specialists, the first course in hospital organization and administration, to be given in 1944, in this city. Dr. Lamela is a member of the board of directors of the School of Tropical Medicine of Puerto Rico.

Deaths

Orville Harry Brown Arcadia Calif., St. Louis University School of Medicine 1905, specialist certified by the American Board of Internal Medicine, member of the American College of Chest Physicians, Royal Society of Medicine, Lecturer and American Association of Pathological Chemists, fellow of the American College of Physicians, assistant in physiology at the University of Kansas 1901-1902, fellow and assistant in physiology at the University of Chicago from 1902 to 1904, assistant professor of pharmacology at the St. Louis University School of Medicine from 1904 to 1907 and assistant professor of medicine from 1910 to 1916, associate director of the Mount St. Rose Sanatorium, St. Louis from 1905 to 1907, superintendent of the Missouri State Sanatorium, Mount Vernon, Mo., from 1907 to 1910, member of the visiting staff of the St. Louis City Hospital from 1910 to 1916, at one time state superintendent of public health of Arizona for many years, editor of *Southeastern Medicine*, received the doctor of philosophy degree from the University of Chicago in 1905, author of "Laboratory Physiology and Asthma," aged 67, died July 26 of carcinoma.

Grover Hewitt Poos Palm Springs Calif., St. Louis College of Physicians and Surgeons 1905, specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology, member of the American Academy of Ophthalmology and Otolaryngology and the Southern Medical Association, fellow of the American College of Surgeons, at one time president of the State Bank at Summit, Ind. Ill., and a member of the school board, served on the examining board of St. Clair County, Ill., during World War I, formerly practiced in St. Louis where he had been an instructor in clinical ophthalmology at the Washington University School of Medicine and on the staffs of the De Paul Hospital, Barnes Hospital and the Evangelical Deaconess Home and Hospital, aged 55, died May 29 of uremia.

Arthur Walter Bingham East Orange N. J., Columbia University College of Physicians and Surgeons, New York 1890, specialist certified by the American Board of Obstetrics and Gynecology, past president of the Essex County Medical Society, fellow of the American College of Surgeons, chairman of the committee on maternal welfare of the Medical Society of New Jersey for many years, consulting obstetrician to the Dover (N. J.) General Hospital, Orange (N. J.) Memorial Hospital and the Presbyterian Hospital, Newark, served as chief consulting obstetrician to the New Jersey Department of Health, in February 1943 was presented with the fourth Dr. Edward J. III Award of the Academy of Medicine of Northern New Jersey, aged 70, died May 18 of carcinoma of the stomach.

John Taylor Watkins, Detroit, University of Michigan Department of Medicine and Surgery, Ann Arbor 1906, specialist certified by the American Board of Internal Medicine, fellow of the American College of Physicians, member of the American Heart Association, at one time associate professor of medicine at the Detroit College of Medicine and Surgery, served as attending physician and vice chief of staff at the Grace Hospital and during World War I as head of the heart and lung division of the medical advisory board, formerly consultant in medicine at the Woman's Hospital and consulting physician to the Highland Park (Mich.) Hospital, aged 59, died May 8 of cerebral hemorrhage.

Walter Allan Minsch Kerrville Texas, Louisiana State University Medical Center, New Orleans 1934, past president and secretary-treasurer of the Limestone County (Ala.) Medical Society, formerly health officer of Limestone County, member of the American Public Health Association and the National Tuberculosis Association, served on the board of directors of the Kerr County Tuberculosis Association, on the staff of the Kerrville General Hospital on the courtesy staff of the Shannon West Texas Memorial Hospital, San Angelo, aged 43, died May 22 of pulmonary tuberculosis and diabetes mellitus.

Henry Burner Anderson Newark, Ohio, Ohio Medical University, Columbus, 1902, for many years surgeon for the Baltimore and Ohio Railroad, aged 65, died May 24.

Raymond West Andrae, Plainfield, Wis., Milwaukee Medical College, 1907, member of the State Medical Society of Wisconsin, aged 61, died June 2, in the State of Wisconsin General Hospital, Madison, of pneumonia.

Claude Wilber Ashley Bloomsburg Pa., Jefferson Medical College of Philadelphia 1932, diplomate of the National Board of Medical Examiners, specialist certified by

the American Board of Pediatrics, Inc., fellow of the American College of Physicians, pediatrician to the Bloomsburg Hospital, aged 38, died May 22, of coronary thrombosis.

William Taylor Barry, Santa Barbara, Calif., Bellevue Hospital Medical College, New York, 1884, past president of the Santa Barbara County Medical Society, formerly president of the city board of education, aged 84, died May 18 of bronchopneumonia, coronary artery disease and cardiac insufficiency.

Frank Clare Bawden Pontiac, Ill., Rush Medical College, Chicago 1902, aged 66, on the staff of St. James Hospital where he died May 26 of cerebral hemorrhage.

Alfred Chapman Benedict South Orange N. J., Columbia University College of Physicians and Surgeons, New York 1901, health officer of South Orange, past president of the New Jersey Health Officers' Association, examining physician for the draft board recently and during World War I, aged 68, died May 28, in the Orange (N. J.) Memorial Hospital of acute bacterial endocarditis, *Streptococcus viridans* and chronic heart disease.

Louis de Milly Blocker Cincinnati, University of the City of New York Medical Department, New York 1889, past president of the Escambia County (Fla.) Medical Society, at one time member of the city board of health of Pensacola, Fla., and past president of the chamber of commerce, medical director of the American Can Company of Cincinnati, aged 76, died May 28 of tumor of the right kidney.

Ray Allen Bowman Elkhart Ind., Indiana University School of Medicine, Indianapolis 1925, coroner of Elkhart County, served during World War I on the staff of the Elkhart General Hospital, aged 40, died May 30 of brain tumor.

John Rufus Bruce, Marshfield Mo., Tufts College Medical School, Boston 1907, for many years secretary of the Webster County Medical Society, served during World War I, served as a member of the city board of health and as county health commissioner and coroner, registrar of vital statistics for the townships of Ozark, High Prairie, Grant, Jackson, Washington, Niangua and Union, aged 59, died May 16.

Julian Cohen Chandler Tampa Fla., Atlanta College of Physicians and Surgeons 1910, aged 65, on the courtesy staff of the Municipal Hospital where he died May 20 of carcinoma of the splenic flexor colon.

William Bicknell Coats, Brainerd Minn., Syracuse University College of Medicine 1886, aged 79, died May 15 of burns received in a gasoline stove explosion.

John Barstow Coryell St. Louis, St. Louis Medical College 1885, aged 73, on the staff of the Alexian Brothers Hospital where he died May 31 of pneumonia as the result of injuries received when struck by an automobile.

John Vance Cowles, Kansas City Mo., Kansas City Homeopathic Medical College 1898, aged 67, died June 11, of leukemia.

James Henry Crouch, Norman, Okla., Medical College of Ohio, Cincinnati 1879, aged 87, died May 6 in the Wesley Hospital, Oklahoma City, of hypertensive heart disease.

Joseph De Horatius Detroit, Regia Università di Napoli, Facoltà di Medicina e Chirurgia, Italy 1905, Detroit College of Medicine 1909, aged 63, died June 21, in the Receiving Hospital of shock and hemorrhage following a skull fracture received during a race riot.

Charles Aloysius Dillon Tulsa Okla., University of Pennsylvania Department of Medicine, Philadelphia 1910, served on the staff of St. John's Hospital, aged 64, died May 29 of heart disease and hypertrophy of the prostate.

Elliott Isaac Dorn Newark, N. J., Long Island College Hospital, Brooklyn 1904, member of the American College of Chest Physicians, for many years director of the tuberculosis clinics of the state department of health, on the staff of the Newark Memorial Hospital, aged 65, died May 26 in the Beth Israel Hospital of cerebral hemorrhage.

George M. Dunaif, Brooklyn, Long Island College Hospital, Brooklyn 1905, aged 64, died May 9.

William F. Eimbeck, New Haven Mo., Washington University School of Medicine, St. Louis 1890, member of the Missouri State Medical Association, aged 71, died April 15 of arteriosclerosis and senile dementia.

Frank Coral Eldred Sparrows Point Md., University of Maryland School of Medicine, Baltimore 1891, member of the Medical and Surgical Faculty of Maryland, aged 75, on the staff of the Church Home and Inn, Baltimore, where he died May 24 of nephritis.

William Crozier Fawcett, Starkweather, N. D., Western University Faculty of Medicine, London, Ont., Canada, 1901, member and past president of the North Dakota State Board of Medical Examiners and the North Dakota State Medical Association, member of the staff of the Mery Hospital, Devils Lake, aged 65, died, June 21, of carcinoma of the sigmoid.

Hubert Flurry, Boonville, Miss., University of Pennsylvania School of Medicine, Philadelphia, 1930, served during World War I, head of the Prentiss County Health Department, formerly acting assistant surgeon in the U. S. Public Health Service and on the staffs of the Veterans Administration facilities in Lake City, Fla., and Aspinwall, Pa., aged 48, died, May 6, of heart disease.

Elsie Fox ⊕ New York, Cornell University Medical College, New York, 1911, aged 58, died, June 30, of cerebral hemorrhage.

Fred Le Grande Gibbs ⊕ St. Louis, Washington University School of Medicine, 1913, served as a captain in the medical corps of the U. S. Army during World War I, a member of the staffs of the Evangelical Deaconess Home and Hospital, Missouri Baptist Hospital and the De Paul Hospital, where he died, June 4, of myocardial infarction and coronary sclerosis, aged 52.

Larkin White Glazebrook, Washington, D. C., College of Physicians and Surgeons, New York, 1890, Long Island College Hospital, Brooklyn, 1890, at one time chief surgeon of the Washington Railway and Electric Company, formerly attending physician to the Central Dispensary and Emergency Hospital and physician to the Washington City Orphan Asylum, aged 75, died, June 3, of heart disease.

James Henry Haberlin, Providence, R. I., Yale University School of Medicine, New Haven, Conn., 1903, formerly on the staffs of the New York Post-Graduate Medical School and Hospital, New York, St. Mary's Hospital, Brooklyn and St. Joseph's Hospital, aged 63, died, May 1, of coronary thrombosis.

Risq Gautus Haddad, Brooklyn, University and Bellevue Hospital Medical College, New York, 1901, served on the staff of the Shore Road Hospital, aged 68, died, May 8, of coronary thrombosis.

Elizabeth K. Miller Halkett, Philadelphia, Woman's Medical College of Pennsylvania, Philadelphia, 1895, aged 82, died, May 23, of heart disease.

Leo Frederick Hall, Helena, Mont., Medical School of Maine, Portland, 1910, member of the Medical Association of Montana, served as health officer of Helena and of Lewis and Clark County, formerly deputy health commissioner and health commissioner of Cuyahoga County, Ohio, at one time health officer of Auburn, Maine, served in the medical corps of the U. S. Army during World War I, formerly on the staff of the Community Hospital, Berea, Ohio, aged 55, died, May 9, of myocarditis, edema and nephritis.

Robert Dudley Harris ⊕ Fulshear, Texas, Medical Department of Tulane University of Louisiana, New Orleans, 1893, served during World War I, aged 73, died, May 9, of cerebral arteriosclerosis.

Henry Gehardt Hartman ⊕ Louisville, Ky., Louisville Medical College, 1907, also a pharmacist, served in the medical corps of the U. S. Army during World War I, aged 61, died, May 6, in St. Anthony's Hospital of injuries received when he was struck by an automobile.

Wesley Romeo Hawkins, Glasgow, Mo., Louisville (Ky.) Medical College, 1892, member of the Missouri State Medical Association, past president of the Howard County Medical Society, aged 74, died, April 17, of myocarditis.

William Allen Hayes, Louisa, Ky., University of Louisville (Ky.) Medical Department, 1908, member of the Kentucky State Medical Association, on the staff of the Louisa General Hospital, aged 65, died, May 22, of coronary occlusion.

Ralph Reid Hendershott ⊕ Tiffin, Ohio, Starling Medical College, Columbus, 1898, president of the Ohio State Medical Association 1935-1936, past president of the Seneca County Medical Society, during World War I was commissioned a captain in the medical corps of the U. S. Army, aged 66, died, May 1, of coronary occlusion.

Henry F. Hill, Baltimore, University of Maryland School of Medicine, Baltimore, 1877, aged 88, died, May 12, in the University Hospital of coronary thrombosis.

Joseph Alton Hoegen ⊕ Wyoming, Iowa, New York Homeopathic Medical College and Flower Hospital, New York, 1915, served during World War I, aged 49, died, May 8, of pulmonary embolism due to hypertensive heart disease.

George H. V. Hunter ⊕ Brooklyn, Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1908, member of the American Academy of Orthopaedic Surgeons, fellow of the American College of Surgeons, served as a captain with the Harvard Unit in the British army in 1916, for many years on the staffs of the Norwegian and Brooklyn hospitals, attending orthopedic surgeon to St. Agnes Hospital, White Plains, aged 63, died, May 21, of carcinoma at his home in Scarsdale, N. Y.

George Oscar Jenkins, Newton, Mass., Harvard Medical School, Boston, 1874, aged 92, died, May 10, of bronchopneumonia.

Fred Garfield King ⊕ Canton, Ohio, University of Wooster Medical Department, Cleveland, 1908, past president of the Stark County Medical Society, past president of the staff of Aultman Hospital, aged 60, died, May 28.

Francis Ronan Mahony, Lowell, Mass., Harvard Medical School, Boston, 1901, also a lawyer, member of the Massachusetts Medical Society, for many years a member and since 1936 chairman of the Massachusetts Board of Registration in Medicine, chairman of the board of health of Lowell, fellow of the American College of Surgeons, senior visiting surgeon, St. John's Hospital, aged 64, died, May 17.

Alban Leo Mann, Elgin, Ill., Bennett College of Eclectic Medicine and Surgery, Chicago, 1883, for twenty-five years health officer of Elgin, aged 83, died, June 1, in St. Joseph's Hospital.

William Moffatt, Utica, N. Y., Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1898, member of the board of directors of the Oneida National Bank and Trust Company, at one time on the staff of St. Luke's Home and Hospital, aged 74, died, May 10, in a New York hospital of carcinoma of the bladder.

Archie Clay Monroe ⊕ Richmond, Va., University College of Medicine, Richmond, 1907, member of the staff of the Stuart Circle Hospital, aged 59, died, May 21, of hypertension.

Nimrod Woodford Moore, Cynthiana, Ky., Medical College of Ohio, Cincinnati, 1881, formerly health officer of Harrison County, aged 85, died, May 26, in the Harrison Memorial Hospital of arteriosclerosis.

Julia C. Cotton Mutchler, Dover, N. J., Woman's Medical College of Baltimore 1908, member of the Medical Society of New Jersey, at one time on the staff of the Norristown (Pa.) State Hospital and the New Jersey State Hospital, Grystone Park, formerly a member of the state legislature and member of the board of health of Dover, school physician, aged 58, on the staff of the Dover General Hospital, where she died, July 16, of carcinoma of the throat.

Emanuel F. Napieralski, Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903, served as a member of the city health department, examining physician for the draft board during World War I, aged 65, died, June 25, of chronic myocarditis and interstitial nephritis.

Lewis Knode Neff ⊕ New York, Bellevue Hospital Medical College, New York, 1886, at one time clinical professor of medicine at the University and Bellevue Hospital Medical College, veteran of the Spanish American War and World War I, member of the old Eighth Regiment of the New York National Guard, formerly director of the medical service at Harlem Hospital, aged 81, died in the Pennsylvania Railroad Station, May 6, of heart disease.

Frank Neufeld ⊕ Davenport, Iowa, John A. Crighton Medical College, Omaha, 1901, also a pharmacist, past president of the Scott County Medical Society, served on the staffs of St. Luke's and Mercy hospitals, a director of the Home Savings Bank, aged 68, died, May 1, of coronary occlusion.

George Charles Oldag ⊕ Paulina, Iowa, State University of Iowa College of Medicine, Iowa City, 1907, past president of the O'Brien County Medical Society, aged 64, died, May 14, in Cherokee of myocarditis and coronary occlusion.

Earl Welbourn Owen, Spencer, W. Va., Vanderbilt University School of Medicine, Nashville, Tenn., 1925, member of the West Virginia State Medical Association, served during World War I, for many years health officer of Spencer, aged 44, died, May 17, in Los Angeles of hypertension.

Norman O. Paulin, Cleveland Heights, Ohio, Western Reserve University Medical Department, Cleveland, 1895, aged 71, died, May 24, in the Cleveland Clinic Foundation Hospital, Cleveland, of coronary thrombosis.

Louis Willard Pease, Chicago Detroit College of Medicine, 1890, member of the Illinois State Medical Society veteran of the Spanish-American War served on the staff of the Veterans Administration Facility, Illinois, Ill., aged 68, died, May 20, of heart disease.

Henry Christian Petersen, Stockton, Calif. College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905, member of the California Medical Association, aged 67, died, May 17, of heart disease.

Benton Sanders Pettus, Athens, Ala. University of Nashville (Tenn.) Medical Department 1892, Vanderbilt University School of Medicine Nashville 1892, member of the Medical Association of the State of Alabama, aged 74 died, May 19, at Birmingham of heart disease.

Thomas Redmond St. Joseph Mo., Rush Medical College, Chicago 1906, an Affiliate Fellow of the American Medical Association, aged 68, died, May 23, of acute coronary occlusion.

Roland H. C. Rhea, Louisville, Ky. Vanderbilt University School of Medicine Nashville, Tenn., 1881, University of Nashville (Tenn.) Medical Department, 1882, aged 84 died, May 22 in the Norton Infirmary of coronary sclerosis and arteriosclerosis.

Clarence Bingham Ripley St. Galesburg, Ill., University of Michigan Department of Medicine and Surgery Ann Arbor, 1902, past president of the Knox County Medical Society, fellow of the American College of Surgeons, served during World War I, chief of staff of the Galesburg Cottage Hospital, member of the staff of St. Mary's Hospital, formerly medical examiner for the Chicago Burlington and Quincy Railroad, aged 66, died, May 6, of coronary occlusion.

Albert Nelson Robinson St. La Belle Pa. Cleveland Homeopathic Medical College, 1904, aged 62 died May 14, of heart disease.

Monroe Leon Rosenberg St. Dallas Texas Baylor University College of Medicine, Dallas, 1932, aged 38 on the staff of St. Paul's Hospital, where he died, May 1, of subacute bacterial endocarditis.

Grant F. Rulifson St. Chicago, Harvey Medical College Chicago, 1904, served on the staffs of the American and Edgewater hospitals, aged 78, died, May 16, of carcinoma of the tongue.

Wesley Claude Runyon, Belleville, Ill., Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1907 member of the medical examining board of the county draft board number 1, served on the staffs of the state institutions in Lincoln, Alton, Peoria and Anna, aged 57, died May 10, of heart disease and cerebral hemorrhage.

William Everett Rushing, Millhaven, Ga., University of Georgia Medical Department, Augusta, 1900, member of the Medical Association of Georgia aged 68, died, May 5, in Augusta of heart disease.

Martha Shalter, Dover, Ohio National Normal University College of Medicine Lebanon, 1889 at one time superintendent of the Tuscarawas Hospital, aged 86, died, May 17, of arteriosclerosis.

Alexander Spingarn, Brooklyn, Columbia University College of Physicians and Surgeons, New York 1901, since 1941 honorary consulting physician and for many years visiting physician to the Kingston Avenue Hospital, formerly a member of the staff of the Methodist Episcopal Hospital, at one time assistant editor of the *Medical Record*, aged 66, died, May 23, of acute coronary thrombosis.

Henry Steudel St. Ansonia, Conn., Christian-Albrechts-Universität Medizinische-Fakultät, Kiel, Prussia, Germany 1889, on the courtesy staff of the Griffin Hospital Derby aged 76, died, May 29, of edema of the lungs, myocardial failure and carcinoma of the stomach.

Andrew Willis Stevenson, Vancouver, Wash., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906, aged 60, on the staff of St. Joseph's Hospital, where he died, May 16, of pneumonia.

Edward R. Stewart, Blair, Neb. Missouri Medical College St. Louis, 1887, past president of the Washington County Medical Society aged 81, died, May 1, of pneumonia.

H. Kathleen O'Connor Sullivan St. Omaha John A. Creighton Medical College, Omaha 1903, past president of the Nebraska Association of Medical Women aged 62, died May 6 in a hospital at Rochester Minn., of carcinoma of the stomach.

Freeman Augustus Tower, Brattleboro, Vt. Tufts College Medical School Boston 1904 member of the Vermont State Medical Society, American Psychiatric Association and the New England Society of Psychiatry assistant superintendent of Brattleboro Retreat, aged 66, died, May 22, of cardiorenal vascular disease.

Union Samuel Ward, New York, Bellevue Hospital Medical College, New York, 1888, aged 80, died, May 1, of heart disease.

Stephen A. Whinery, Grand Rapids, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1890, aged 76, formerly on the staff of St. Mary's Hospital, where he died May 1 of coronary thrombosis.

Charles Fiske Wood, Westfield, N. J., New York Homeopathic Medical College and Hospital, New York, 1901, at one time a lieutenant in the U. S. Navy, formerly medical inspector for the schools of Westfield and member of the board of health, at one time member of the board of health of Saginaw, Mich., served on the staffs of the Montclair (N. J.) Community Hospital and the Rahway (N. J.) Hospital, aged 66, died, May 2, of coronary thrombosis.

Herbert Samuel Worthley, Joliet, Ill. Northwestern University Medical School, Chicago 1893, member of the Illinois State Medical Society served on the board of St. Joseph's and Silver Cross hospitals, for thirty-seven years medical examiner for the Metropolitan Life Insurance Company, aged 75 died, May 7 of cerebral hemorrhage.

Edgar Williams Young St. Petersburg, Va., Baltimore Medical College, 1911 served overseas during World War I and was decorated with the Order of the Purple Heart, aged 55 on the staff of the Petersburg Hospital, where he died, May 22 of pneumonia.

Alfred Angelo Zangrilli, Pittsburgh, Jefferson Medical College of Philadelphia 1931, member of the Medical Society of the State of Pennsylvania medical examiner for draft board number 12, school physician, on the staff of the Pittsburgh Hospital aged 43, died, May 27, of coronary occlusion.

Avrum Herman Zeiler St. Los Angeles, Columbia University College of Physicians and Surgeons, New York, 1905 specialist certified by the American Board of Pathology, Inc. on the staffs of the California Hospital, Hospital of the Good Samaritan Queen of Angels Hospital and the Cedars of Lebanon Hospital, where he died, July 16, of carcinoma of the colon, aged 61.

William Walter Zwick, Riverside, N. J., University of Louisville (Ky.) Medical Department 1919, served during World War I at one time a medical missionary in China, in 1924 had been appointed university physician to the University of Kentucky Lexington, public school physician and examining physician for the local Selective Service Board, aged 54 died, May 23, in Philadelphia of coronary occlusion.

DIED WHILE IN MILITARY SERVICE

Ralph Clarke Bradley St. Philadelphia University of Pennsylvania School of Medicine, Philadelphia, 1929 served as an instructor in pharmacology at the Temple University School of Medicine for nine years flight surgeon for the Pennsylvania National Guard, captain in the medical corps Army of the United States, aged 44 died April 28, in the Tilton General Hospital, Fort Dix N. J., of malignant lymphoma of the stomach with metastasis.

Earl V. Ferguson, Cincinnati, University of Cincinnati College of Medicine 1930 member of the Ohio State Medical Association served on the staffs of the Christ, Bethesda and Cincinnati General hospitals lieutenant commander, medical corps U. S. Naval Reserve aged 39 died June 20 in the U. S. Naval Hospital, Pearl Harbor T. H. of purpura hemorrhagica.

Manuel Heine Shear St. York Pa. Hahnemann Medical College and Hospital of Philadelphia 1932 member of the Medical Society of the State of Pennsylvania captain in the medical reserve corps of the U. S. Army aged 35 killed July 24 1942, in an airplane accident in the African area.

Lucius Townshend Wing New York Harvard Medical School Boston 1939 diplomate of the National Board of Medical Examiners first lieutenant in the medical reserve corps of the U. S. Army aged 28 died May 24 in the European area.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Pharmacists Atropine Negligently Included in Filling Prescription for Tonic—The defendant drug company on June 25, 1939 filled a prescription for a tonic in capsule form given the plaintiff by Dr Sibley, which, among other things, called for phenacetin, arsenic acid and strychnine sulfate. The size of the dose called for by the prescription the reported case does not make clear, although the prescription directed the taking of four capsules daily. The plaintiff took two capsules on the 25th. His wife then noticed that the pupils of his eyes were dilated. He took capsules in the morning and at noon on the 26th. While eating his noon meal he choked on a piece of meat because he could not swallow. His vision became impaired and by afternoon he was unable to read numbers on freight cars or to distinguish people. He began to stagger, his throat was dry and he could hardly talk. The plaintiff consulted his physician that afternoon who after examining him, as also did the physician's son another physician ordered him to discontinue taking the capsules and gave him bromides "to settle his nerves." The physician meanwhile had been assured by the drug company that his prescription had been correctly filled. The next day the attending physician called in Dr Tripp, an eye and ear specialist and Dr Krigsten. The four physicians believed that the symptoms all pointed to an acute poisoning from atropine. These physicians, and one other physician also called by the plaintiff as a witness in the suit he instituted against the drug company stated also that there was no probability that the drugs prescribed by Dr Sibley would or could cause the plaintiff's condition. The plaintiff subsequently brought suit against the drug company, alleging that it had negligently included in the capsules called for by Dr Sibley's prescription "atropine, a poisonous and injurious drug not called for in said prescription." From a judgment for the plaintiff the drug company appealed to the Supreme Court of Iowa.

The principal contention of the drug company on appeal was that the evidence adduced before the trial court was insufficient to show that the capsules contained atropine. In addition to the testimony of the five physicians referred to, a pharmacist of the defendant drug company, who had filled the prescription, testified that in the pharmacy of the defendant arsenic, strychnine and atropine were kept together in different bottles in the same compartment. There was testimony that the bottles and tablets of the three last named drugs were similar in size and shape. Also there was testimony by Professor Coss, head of the Morningside College chemistry department, that he had made a chemical analysis of some of the capsules and that one of the tests he performed on the capsules was "Vitali's test," which was positive for atropine or the atropine group, and that in his opinion there was atropine in the capsules. This witness stated also that he performed a biologic test by putting a solution from the capsules in one of his eyes and that the solution dilated the pupil and indicated that the capsules contained atropine or compounds of the atropine group. The defendant called as a witness in its behalf Dean Teeters of the Pharmacy College of Iowa University, who denied much of Professor Coss's testimony. He testified that he performed Vitali's test (which he said was the best for atropine) on the contents of three of the capsules and found no atropine. He testified also that it was impossible "to make a chemical examination that would be absolutely trustworthy" of the combination of prescribed drugs. On cross examination Professor Coss stated that hyoscyamine and hyoscyne, with atropine, are related drugs of the atropine group and that he could not be positive from his tests that the capsules contained atropine rather than hyoscyamine or hyoscyne, that these three drugs of the atropine group have the same properties and would have the same effect, although they are separate drugs. On the basis of this testi-

mony brought out in the cross examination the drug company claimed that the plaintiff had failed to prove that the capsules contained atropine.

That this argument, said the Supreme Court, is somewhat technical is disclosed by the fact that the chemical formula for hyoscyamine is identical with that for atropine, according to the U. S. Pharmacopeia, of which we take judicial notice. We think that there was sufficient evidence that the capsules contained atropine. The plaintiff's medical witnesses testified that the plaintiff, who had taken four of the capsules, showed the characteristic symptoms of atropine poisoning. The jury could have found that, owing to the appearance and location in the prescription counter of the tablets and bottles containing arsenic and strychnine, which were prescribed, and those containing atropine, the latter may have been included. There was no evidence that the drug company kept on hand any hyoscyamine or hyoscyne, the other two drugs of the atropine group to which Professor Coss referred, nor that the capsules in fact contained either drug, but only Professor Coss's admission that either would produce similar results in Vitali's test. Dean Teeters, the expert witness called by the defendant, did not claim that either of the other two drugs of the atropine group was present in the capsules. It was not necessary for the plaintiff to prove conclusively the presence of atropine in the capsules or to exclude to a certainty every other suggested poison. The evidence was such as to make the plaintiff's theory of atropine poisoning reasonably probable—not merely possible—and more probable than any other theory based on such evidence. This is sufficient.

At the trial counsel for the plaintiff asked a medical witness "May there be permanent effects of atropine poisoning even though no organic trouble can be demonstrated?" It was proper, said the court, for the trial court to permit the expert witness to answer even though the answer was "It is possible." While an expert may not express a mere guess or conjecture, he may testify to what might have been the cause of a certain result. An opinion as to what was the possible cause of a given result is not too uncertain.

During the trial the plaintiff propounded a long hypothetical question to Drs Sibley and Krigsten in which one of the assumed facts was that the "Vitali test as made by Professor Coss was positive for atropine and compounds of the atropine group." The drug company objected to the question because any answer to it would be based in part on the opinion of Professor Coss, an expert witness. It was proper, said the court, for the trial court to permit an answer to this question. While it is true that the opinion of an expert should not be based on the opinion of another expert witness, facts testified to by one expert may properly be included in a hypothetical question propounded to another expert. The quoted portion of the question referred to a fact and not an opinion of an expert witness and therefore was proper.

For the reasons stated the judgment in favor of the plaintiff was affirmed—*Cody v. Toller Drug Co., 5 N. W. (2d) 824 (Iowa, 1942)*.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in the continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of date desired cannot be filled. Request should be accompanied by check to cover postage (6 cents if one or 14 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but can be supplied on purchase order. Reports as a rule are the property of authors and can be loaned for private use only from them.

Titles marked with an asterisk (*) are abstracted below.

Normal Appearing Gallbladder. (Report of 32 Operated Cases with Long Follow Up). J. R. Verbricke Jr.—p. 190

Influence of Vitamin C on Wassermann Fastness—According to Ruskin vitamin C apparently enhances the spirocheticidal effect of bismuth and the trypanomicidal effect of antimony. With all other factors equal the addition of bismuth cevitate produced negativity in 7 out of 10 syphilitic patients with positive Wassermann fastness. Vitamin C and glutathione influence the capacity for spirochetes and trypanosomes to take up arsenic antimony bismuth and gold. Vitamin C acts as a detoxifier of antimony arsenic and bismuth in the reduced state and can enhance the spirocheticidal and trypanosomal action of these metals during the process of oxidation. Bismuth cevitate may be considered an important addition to the therapy of Wassermann fast syphilis.

Preliminary Clinical Observations on Use of a Million Volt Roentgen Rays. R. Dresser—p. 536

Bleeding in Hiatus Hernia—Sahler and Hampton state that a study of hiatus hernia carried on at the Massachusetts General Hospital for a period of ten years brought out two important points. One is that hemorrhage may be a symptom of hernia, the second that the incidence of hiatus hernia is considerably higher than has been appreciated. The diagnosis of

hiatus hernia is dependent on two roentgenologic points: an asymmetrical relationship between the lower end of the esophagus and the herniated fundus of the stomach, and a narrowing of the lumen where it passes through the diaphragm. A soft tissue mass in the lower mediastinum should suggest the possibility of hiatus hernia as well as the usual differential diagnosis of tumor abscess.

Ghons Tubercle—According to Bloch the term Ghons tubercle has been universally accepted as signifying the calcified single or multiple remnants of a tuberculous lesion resulting from a primary infection acquired in childhood. This interpretation is made regardless of the age of the patient in whom such a lesion is found; its origin is placed back in the early years of life from the adolescent and senile age period alike. Bloch points out that authors from different continents studying tuberculosis in various races have demonstrated that calcifications are found more frequently in old than in young persons and that there is a steady rise in the frequency of such findings with increasing age. Observations in case finding programs in Chicago demonstrated the greater incidence of calcified foci in higher age groups. The majority of such lesions originating during adult life can be traced to exogenous superinfection of individuals known to have been exposed to infection as adults. Serial roentgenographic evidence of the development of calcifying foci in adults is presented. They cannot be differentiated from childhood (primary) lesions. A reevaluation of the so-called Ghons tubercle or primary tuberculous calcification is needed. In the light of the present knowledge the only justifiable interpretation to be placed on the finding of a calcified tuberculous lesion by roentgen examination is that it represents the innocuous residual of a tuberculous infection either primary or reinfection at some prior time either in childhood or adulthood without its being possible to determine the time at which the infection occurred. The term 'Ghons tubercle' should be dissociated entirely from the time element and applied to all small calcifying or calcified tuberculous foci regardless of age or it is to be retained as signifying the residuals of a childhood infection; it should be applied only when the calcified residuals are found in a child.

Urea-Sulfonamide Mixtures in Wound Therapy—Holder and Mackay show that urea (carbamide) acts in a number of ways to enhance the action of the sulfonamides. They mention the removal by urea of gross sulfonamide inhibitors or of the source of such inhibitors in the form of necrotic tissue pus and tissue exudates. Urea increases the solubility of the sulfonamide drugs. It urea had none of its other known advantages its value as a diluent for the sulfonamides would almost be sufficient reason for its addition to these drugs. The degree of active cellular defense within the wound is aided by urea. It is probable that the hypertonicity of the solution leads to diapedesis and an increase in the resection within the wound tissues. Urea-sulfonamide mixtures have been most satisfactorily employed for first aid in contaminated traumatic wounds.

Experience indicates that with their use formal surgery may be safely delayed long after twelve hours have elapsed. In the handling of wounds resulting from military action this extended period during which a wound may be kept from becoming infected provides for delay in evacuation of wounded and their transportation to facilities allowing adequate treatment. It permits the adequate treatment of shock during the initial period, thereby rendering the patient the best possible risk for surgical treatment. Wounds in which tissue loss prevents primary closure are treated by daily application of urea-sulfonamide mixtures after suitable surgery, including adequate debridement. This is immediately productive of clean, healthy, rapidly growing granulation tissue which permits early successful skin grafting with attendant reduction of disability from scar tissue contraction as well as improvement in the final cosmetic results. Wound therapy with urea-sulfonamide mixtures is simple and inexpensive.

Pathogenicity of *Bacteroides Melaninogenicus*—Weiss maintains that *Bacteroides melaninogenicus*, a small, gram-negative, anaerobic, nonsporulating, black pigment producing germ, should be regarded as a pathogen which is of importance in surgical infections. He has isolated it in combination with other aerobic and anaerobic bacteria from 45 surgical cases representing various infected wounds, lesions of the pleura and peritoneum as well as of the gastrointestinal, respiratory and genitourinary tracts. Others have cultivated it from the blood stream during puerperal infection. The author found it at necropsy in the heart's blood, the peritoneum and the visceral organs. Experimentally he has shown that it possesses a fibrinolysin which permits it to dissolve human blood fibrinogen, thus interfering with one of the essential defense mechanisms of the inflammatory process, local fixation of micro-organisms. In cultures it produces a putrid, foul odor and together with the anaerobic *Streptococcus putrificus* is responsible for the unpleasant odor of some types of pus. Strains of *B. melaninogenicus* were recovered from human lesions which, if inoculated within a few days after cultivation, were pathogenic for rabbits and mice. Intradermal injection produced in the former intense local inflammation, dermonecrosis and occasionally death. Previous damage of the tissue by a bacterial toxin enhances the dermonecrotic properties of the germs. The use of mucin as a menstruum for suspending the bacteria supplies them with a capsule, thus augmenting their pathogenicity and invasiveness. *B. melaninogenicus*, like *Bacteroides funduliformis* and certain other members of the genus *bacteroides*, may therefore be regarded as an "opportunistic" which must find conditions suitable for invasion and multiplication.

Meningococcal Meningitis—Awe and his associates report 50 cases of meningococcal meningitis which were treated at the Naval Hospital of San Diego during 1942. Two deaths occurred, one twenty minutes, the other four hours after admission. These are not chargeable to therapeutic failure, as 1 received no drugs, the other only one dose. The fact that 11 patients were comatose and 27 were stuporous, irrational or otherwise disturbed mentally indicates that the cases were not unusually mild. Fifteen patients received serum and sulfapyridine and 31 only sulfapyridine. No difference was noted in the

patients treated with serum as compared with those not receiving it, save the high incidence of troublesome serum sickness. Therapeutic success depended on early and large doses of sulfapyridine, 12 Gm intravenously in the first twenty-four hours. Adequate fluid intake, 3,000 cc intravenously daily, prevented serious drug complications. All factors, excepting avitaminosis, which are accepted as fostering outbreaks of meningitis, were noted in 32 marine recruits: (1) rapid hardening of physically soft men, (2) mobilization of large numbers of susceptible men in crowded quarters, (3) prevalence of colds, (4) temporary overload of immunologic processes (inoculations against typhoid, tetanus and the like), (5) an underlying carrier state, (6) excessive heat and dust. With early diagnosis and adequate treatment the mortality and complications of meningococcal meningitis will approach zero. Sulfonamides alone, in large doses with ample fluid, provide adequate treatment. Serum is unnecessary and impractical for military use. Sporadic cases are to be expected in men subjected to the conditions found in recruit training. Chemoprophylaxis is recommended in an epidemic of meningococcal meningitis, and alterations in the training program may be necessary.

Photophthalmia Due to Rays of Welding Arc—Benson directs attention to the problem of exposure of the eyes to the radiant energy of the welding arc with the resultant photophthalmia, actinic ray ophthalmia or "flash." This type of eye injury is frequent in shipyards and in plants where welding plays a large part. It is not the welder who is the most frequent victim of his own arc but the workmen engaged in work near the welder. The welder protects himself with his hood. He may, however, receive an actinic injury from the arc of another welder near him or from his own "accidentally struck" arc while his own hood is raised. After exposure to the arc a latent period ensues which may vary from two to fifteen hours. The lesion then manifests itself with a sudden onset of intense photophobia, lacrimation and a burning sensation in the eyes. The most frequent complaint is that of a feeling of "sand in the eyes." The lesion is bilateral, although at times the symptoms will appear earlier in one eye than in the other, in the present series the majority of "one-eyed flashes" were found to be caused by foreign bodies. Moderate dilatation of the conjunctival vessels is present, but this congestion is usually limited to the area of the palpebral fissure. Prevention can be accomplished by protecting the eyes with shields, hoods and goggles. Seventy-three cases were treated with a 2 per cent butyn sulfate and a 1 per cent diothane hydrochloride, 447 cases were treated with a solution containing 0.25 per cent nupercaine hydrochloride and 0.5 per cent neosynephrine hydrochloride as the active principles. The nupercaine was used because of its relatively prolonged anesthetic action. Neosynephrine was added to overcome the vasodilatation and to attempt a partial neutralization of the contraction of the pupils accompanying many actinic ray lesions. The nupercaine-neosynephrine was dissolved in a zephiran 1:5,000 aqueous base to decrease the surface tension of the solution, for better penetration and to furnish an antiseptic medium. About 2,500 additional cases have been treated by the nupercaine-neosynephrine routine. The treatment has not appreciably decreased the duration of the reparative process. It gave considerable symptomatic relief and helped return men to their work with a minimum of lost time and with no apparent permanent injury.

An asterisk (*) before a title indicates that the article is abstracted from a single case report and trials of new drugs are usually omitted

Brain, London

66 188 (March) 1943

Studies of Neuro-muscular Disorders. Myocardial Blood Cholesterol and Effect of Prostigmine in Myasthenia Gravis and Progressive Muscular Atrophy. G. Odum, C. K. Russel and D. McEachern—p. 1.
Subdural Empyema. C. S. Kubik and R. D. Adams—p. 18.
So-Called Laryngeal Epilepsy. C. W. M. Whitty—p. 41.
Genetic and Familial Aspects of Dystrophia Myotonica. O. Maas and A. S. Paterson—p. 55.

Subdural Empyema—Kubik and Adams review 14 cases of subdural empyema. The sources of infection were paranasal sinusitis in 12 cases, otitis media in 1 case and bronchiectasis with metastatic infection in 1 case. The symptoms in the cases complicating sinusitis consisted of exacerbation of chronic sinusitis, orbital swelling, headache, rise in temperature, stiffness of the neck, drowsiness or stupor and focal neurologic signs. Hemiparesis or hemiplegia occurred in every case. Paralysis or contralateral deviation of the eyes nearly always developed. Aphasia was observed in most cases of left-sided empyema. Jacksonian seizures were fairly common. Spinal fluid pressure was nearly always increased, ranging from normal to the equivalent of 370 mm. of water. Cell counts generally ranged from 150 to 600 per cubic millimeter with polymorphonuclear leukocytes predominating. The sugar content of the spinal fluid was normal. The total protein ranged from 49 to 186 mg. per hundred cubic centimeters. No organisms were found in smears or culture. Except for absence of sinus infection and orbital swelling the clinical manifestations in the 2 other cases secondary to otitis and to bronchiectasis, were similar to those complicating sinusitis. The course was rapidly progressive. In 12 cases death occurred six to twenty days after onset of headache, and two to five days after focal signs were first observed. In 2 cases recovery took place after drainage of the empyema. Infection of the subdural space took place by direct extension through the dura or as a result of thrombophlebitis involving the venous sinuses, usually the superior longitudinal. The subdural pus covered the greater part of the lateral surface of the hemisphere, the greatest amount being situated over the lateral surface of the frontal lobe. There was a localized sub-arachnoid exudate conforming in its distribution to that of the subdural exudate but scarcely any generalized leptomeningitis. In the underlying cortical gray matter there was severe ischemic necrosis and in most cases thrombosis or thrombophlebitis involving the subarachnoid veins. Surgical treatment should consist in drainage through a lateral frontal craniotomy and not through the frontal sinus or a mastoidectomy wound. The operation is simple and quick and if the results are negative little or no harm is done provided the brain is not explored.

So Called Laryngeal Epilepsy—Whitty reviews a condition originally described by Charcot as laryngeal vertigo. Theories on the etiology of the condition fall into two main groups, those which regard it as primarily neurologic and those which regard it as primarily cardiovascular. In the first group is Charcot's theory of reflex vertigo and the epileptic theory of origin while in the second appear the theories of cerebral anoxemia, venous congestion and cardiac astyole. The condition occurs in middle aged men of plethoric type and is associated with a laryngitis or bronchitis. A previous personal or family history of epilepsy may occur but is not common. The presenting symptom is an attack of dizziness or loss of consciousness preceded by a tickling sensation in the larynx and a cough which may be slight or severe. Epileptiform movement may occur during the attack but a more constant feature is a slight mental confusion afterward. About a fourth of the cases appear to recover or remit following local treatment of any abnormality which may be present in the upper respiratory tract. Four cases are reported in detail. It is suggested that the condition is primarily epileptic. The name laryngeal epilepsy would appear more suitable than that under which the condition is at present most widely known.

Dystrophia Myotonica—Maas and Spencer Paterson base their study of the familial aspects of dystrophia myotonica on an analysis of 94 affected families. Dystrophia myotonica is essentially the same as myotonia congenita and paramyotonia. The disease is more frequent than is generally supposed. In the families of the 94 propositi 261 individuals showed definite signs of the disease while another 285 had suggestive symptoms. Although the disease is frequently noticed for the first time in the third and fourth decades of life the authors have observed it in persons aged 14, 12, 9, 8, 6, 5, 4 and 3. Although patients generally die by the age of 50 they have occasionally found one comparatively well beyond the ages of 60 and 70. In certain families in which for the most part symptoms were slight members were often remarkably prolific. However mental defect and other symptoms affecting earning power combined with atrophy of the testes caused a definite fall in the number of children in later generations. There was a high incidence of miscarriage and infantile mortality which was probably due to the disease process and not merely to the low social status of the families affected. Twinning appears to be particularly frequent and thus may be related to a nova affecting the germ plasma. Although patients are occasionally found of high social status most families are low in the social scale. The disease is transmitted in a dominant manner; it is inherited from male and female with equal frequency. Consanguinity is probably not infrequent in early generations. There is evidence that in many families the disease comes on at an earlier age and in a more intense form in successive generations. It was also usual for younger members of a sibship to develop the disease at an earlier age than the older sibling and in a more severe form.

Physiology of Chronic Nephritis. J. M. Hayman—p. 291.

Hippuric Acid Excretion Test in Pregnancy. L. Sloman—p. 293.

Precipitation in Stored Human Serum. Preliminary Note on Factors Concerned. P. M. de Burgh and R. N. Lyons—p. 298.

Nomographic Method for Determination of Urea Clearance—Davis has correlated the urea clearance test with clinical and other observations in 54 cases involving 67 tests. By comparison with other tests and by follow-up investigation of clinical histories a careful estimation of the test has been possible. The importance of giving urea by mouth to subject the kidney to load or stress is emphasized. The simple Van Slyke test by omitting this factor is of less value than the modified urea clearance which is described. All aspects of a case must be considered before final conclusions are reached. A simple nomographic chart is presented which will allow the clinician to determine from all available data the true clearance value. The chart has four scales. One scale marked V indicates the volume of urine in cubic centimeters excreted each minute. The scale marked U records urea concentration (grams of urea per hundred cubic centimeters). The B scale shows the blood urea level (milligrams of urea per hundred cubic centimeters of blood). The C scale indicates the blood urea clearance as a percentage of the normal value. To determine clearance (C) a straight line is placed through values U and B which intersects a central unscaled line. Then a straight line is placed through this point and value V. The point of intersection of this line with the C scale gives the value of C that is clearance. This nomograph chart eliminates all mathematical formulas. The author concludes that the urea clearance test is reliable and accurate and in many cases provides the only guide to renal damage. Because other means of biochemical assessment often prove misleading older methods should be discarded. The urea clearance test should be employed in assessment of prognosis or of fitness for operation. The test appears to be of great value in chronic nephritis and prostatic enlargement in which urea concentration and blood urea level may be misleading.

 *Pneumonic Plague Recovery in Proved Case B M Clark and S Goldberg—p 57
 Plasmocytosis of Bone Marrow Associated with Metastatic Carcinoma E Miller—p 61

Recovery from Pneumonic Plague—According to Clark and Goldberg the mortality of pneumonic plague may be considered as 100 per cent. The authors report an outbreak which, although the number of cases involved was small (11 in all), was potentially serious as it took place in a crowded location in the native part of a town in the northern Orange Free State. The measures taken to control the outbreak consisted in quarantine and the giving of live avirulent vaccine. Concentrated serum was given as a prophylactic measure to close contacts. Antrodent work was carried out in the area. The patient who recovered was an old woman who belonged to the same household in which 4 fatalities from pneumonic plague occurred. She had the same symptoms as the others. She had been given 1 cc of live avirulent vaccine and 50 cc of antiplague serum as a prophylactic measure five days before the onset of her illness. She was treated early with large doses of serum, 400 to 500 cc intramuscularly and subcutaneously. She had remittent pyrexia for a period of a week and was acutely ill but finally recovered. Bacteriologic evidence of pneumonic plague was found in the sputum.

 *Twenty Years' Experience in Puerperal Eclampsia A J Guiryo, R Dubrovsky and N O Di Fouzo—p 394

Treatment of Puerperal Eclampsia—Guiryo and his associates review 233 cases of puerperal eclampsia observed in the course of twenty years. The maternal mortality was 6.43 per cent and the fetal mortality 9.43 per cent. When the dead and macerated fetuses whose death was caused by gestosis and other causes rather than by the eclampsia are included, the fetal mortality reaches 15 per cent. Cesarean section is losing ground as a therapeutic method in puerperal eclampsia. It is indicated only in exceptional cases. Prophylactic treatment during pregnancy by hygienic measures and a well chosen diet continue to be the essential factors in the reduction of the maternal and fetal mortalities from puerperal eclampsia. The outpatient departments of the maternity hospitals play an important part in this prophylaxis. At the maternity hospital with which the author is connected satisfactory results were obtained with Stroganoff's prophylactic method, which combines morphine, magnesium sulfate and venesection. Absolute isolation is enforced to keep away all excitement, necessary manipulations are carried out under mild anesthesia, the patient is kept warm, and hypnotics of low toxicity are administered.

 Treatment of Obesity from Biologic Point of View R Trumpp—p 313
 Treatment of Hidrademitis Suppurativa Axillaris W Schuchard—p 315

The Clinical Picture of Typhus—Frequently the onset is abrupt after a period of incubation of from twelve to fourteen days. There is a rise in temperature on the first day up to 102.2 F and a severe headache. The temperature falls but not to normal on the second and third days and this is followed by a new and even higher rise for about eight days. The rash appears on the third to the fifth day. Brauer's eraser phenomenon (fine scales of the horny layer of the epidermis may be removed by rubbing with the finger) precedes the desquamation, which begins between the twelfth and the fifteenth day. Yellow pigmentation of soles and palms may be present. Disturbances of the central nervous system are important. The

course of the disease depends on the behavior of the heart and circulation. These are indicated by the changes in the electrocardiograms. The spleen is enlarged during the first half of the febrile phase. Tracheitis and bronchitis are frequent. There is a mild leukocytosis. Decrease or absence of eosinophils corresponds with the degree of infection. Disturbances of chlorine and water metabolism are manifest by the degree of thirst. Abnormal breaking down of albumin results in increase in residual nitrogen. Occasional anomalies such as absence of the rash and of cerebral and circulatory disturbances may occur in an otherwise typical course. A strong active immunity for a long period follows a single attack. Favorable results were obtained with oral administration of diazotized prontosil (4 sulfonamide 2-4 diaminoazobenzol, 6 carbonic acid). Symptomatic treatment however, is recommended. Eradication of lice as hosts of *Rickettsia prowazekii* is decisive in the combat against an epidemic, although active and passive vaccination is of value.

Psittacosis Pneumonia—Pneumonia with few symptoms and little sputum is the essential feature of psittacosis in man. The bronchi may be considered as the port of entrance for the infection and the disease may be transmitted by inhalation of infectious dust. Although bacteriologic diagnosis may fail, the x-ray film shows certain changes which together with an atypical clinical picture facilitates the diagnosis. Roentgenograms show single or multiple fluffy shadows of the type of central pneumonia or of an entire lobe. Since similar x-ray pictures may be seen in grippal pneumonia, the roentgenogram by itself is not sufficiently typical to make a diagnosis. The roentgenographic shadows are evanescent and there is an absence of inflammatory symptoms on the part of the pleura and the pericardium. The discrepancy between the meager or absent clinical findings and roentgenographic changes is characteristic. Psittacosis in man is probably a familial disease since several members of the same family may be affected at the same time or at short intervals.

 *Experiences in Neurosurgical Treatment of Megacolon V Ripant—p 934
 Perforated Gastric Ulcer of the Greater Curvature E Sipos—p 949
 Problem of Defects of Mesentery T Hornitzki—p 952

Neurosurgical Treatment of Megacolon—The cause of idiopathic megacolon is dystonia of the sympathetic nervous system, the mechanism of which is not understood. The clinical picture of idiopathic megacolon is not the same in children and in adults, although the pathogenesis and the anatomic changes are the same. Conservative treatment in childhood is not satisfactory. Conservative treatment, however, is indicated during the first year of life when surgical intervention is contraindicated. Neurosurgical treatment of unilateral inferior lumbar sympathectomy is, however, advisable even at this period of life if the conservative treatment fails. The bilateral resection of the dilated segment may be the method of choice, but it will fail in the presence of atonia combined with dilatation of the ampulla recti. Kummel-Kirschner's invagination method is indicated in such cases. The Delor-Gomard-Merz method combines the advantages of unilateral resection with exteriorization of the colon and later anastomosis. The neurosurgical treatment, while the anatomic changes in the colon are not pronounced, is the logical conclusion to the concept that idiopathic megacolon is a manifestation of dystonia of the vegetative system in the sense of sympathetic hypertonia. Favorable results were obtained in 4 out of 5 cases in which neurosurgical treatment was practiced. It consisted in bilateral inferior lumbar sympathectomy combined with resection of the superior hypogastric plexus in the first and with additional resection of the inferior mesenteric plexus in the second case, or unilateral inferior lumbar sympathectomy in the third and fourth cases of two infants. It was demonstrated that the inferior lumbar sympathectomy will not replace the resection of the superior hypogastric plexus. The bilateral inferior lumbar sympathectomy alone will be sufficient only in early cases in which only the sigmoid flexure is involved. Both the neurosurgical and the radical method are justified in surgery of the megacolon.

Book Notices

Neurology and Thoracic Surgery Prepared and edited by the Committee on Neurology and Thoracic Surgery of the Committee on Surgery of the Division of Medical Sciences of the National Research Council. Prepared and edited by the Subcommittee on Neurology. Howard C. Naffziger (Chairman) With contributions by Francis C. Grant, J. Crafton Love and John F. Scarff. **Thoracic Surgery** Prepared and edited by the Subcommittee on Thoracic Surgery. Everett A. Graham (Chairman). **Military Surgical Manuals** Volume VI. Cloth. Price \$2.00. Pp. 215 with 74 illustrations. 221 510 with 50 illustrations. Philadelphia & London: W. B. Saunders Company, 1943.

This is an important book on a subject that is well treated and most briefly and comprehensively presented. The student must remember in reading this book that we are dealing here almost exclusively with traumatic conditions of the central nervous system as well as of the peripheral nervous system. It cannot be too strongly emphasized that any one who masters the book as it is outlined is not necessarily a neurologic surgeon and surely this little volume does not intend to create that impression.

The prophylactic treatment particularly in reference to immunization should be forcefully impressed on any one who reads the book because it certainly is a step in the right direction. The use of the sulfonamide drugs cannot be too highly emphasized because of the potentialities of making a twenty-four hour wound or older one possible for primary suture.

The treatment of gunshot and other injuries to the scalp skull and brain except for the factor mentioned is the same as has been carried out for many years and nothing particularly new has been added. One thing that is emphasized is the advisability of transportation of these patients to a hospital where proper neurosurgical therapy can be instituted. Transportation by plane is emphasized and the dangers are noted.

The treatment of injuries to the spinal cord is comprehensive although the reviewer does not agree in its entirety with the contents of the book. Traumatic spine conditions may be operated on irrespective of the Queckenstedt test. No one can determine clinically whether a cord is completely severed or whether there is a physiologic block.

The chapter on intervertebral disks in military service is no different than in civilian life. This is one of the most abused diagnoses in medicine and unless a myelogram is made the diagnosis is always questionable.

Peripheral nerve injuries are handled quite well nothing new having been added since World War I. Unfortunately some of the newer methods in the treatment of peripheral nerve injuries are not incorporated in the text. True these have not been proved clinically but an addendum may be made after proof of the clinical value of the new type of treatment is established.

The section dealing with infections of the scalp skull and meninges is comprehensive. Certainly after reading this section physicians should be conscious of the fact that infections of the central nervous system require excellent judgment and proper timing relative to the institution of therapy. The charts for examination and recording purposes are ideal and should be studied carefully and utilized in their entirety.

This book, therefore, is a complete treatise on injuries to the central nervous system and peripheral nerves. To all surgeons who will be confronted with this type of work whether in military or in civilian life this book is highly recommended.

Textbook of Periodontia (Oral Medicine) By Samuel Charles Miller DDS, F.A.C.D. Associate Professor of Periodontia in Charge of Periodontia Department New York University College of Dentistry New York. An Introduction by John Oppie McCall AB DDS FAAP Director Murry and Leone Guggenheim Dental Clinic New York. Second edition. Fabrikoid. Price \$9.00. Pp. 733 with illustrations. Philadelphia: Blakiston Company, 1943.

It is significant of the progress of periodontia as a science that after only four years the author felt impelled to revise his former textbook to include valuable new findings and improvements in technique. This volume is comprehensive not only as to all phases of dental health but as to its relation to physical health as well. The increasing life span has brought gerodontia (dentistry for the aged) to the fore as an obligation of the practicing dentist. The highest goal in oral health service may

be achieved by the dentist only through sound knowledge of disease processes and efficient methods for their treatment.

The conquest of periodontal disease is an accomplished fact, where heretofore pyorrhea was considered incurable. Prevention of the disease is of primary importance. It not too far advanced it may be cured. This book gives an adequate presentation of the principles of treatment from therapeutic and surgical points of view.

Every chapter treats its subject in minute detail, with illustrations and chemical formulas. Diagnosis and treatment cover physiologic as well as dental symptoms and diseases. Laboratory procedure includes metabolism and blood chemistry, with colored illustrations of normal development of blood cells contrasted with pathologic shifts. Also tests for vitamin C content of the blood plasma, urinalysis and skin tests for allergic reactions. All conditions of periodontal pockets are illustrated with the proper instruments and their use as the case requires.

An exceptional chapter is the one on traumatic occlusion its detection and correction. So many dental diseases have been traced to traumatic occlusion that all branches and specialties of dentistry are readily recognizing the value of occlusal coordination. A comparative study of X-ray films over a period of years of teeth having no occlusal adjustment shows clearly the condensation of bone to resist strain. The alveolar support cannot resist strain indefinitely so teeth eventually loosen and require extraction even though they are vital and examination of the socket reveals diseased bone. Because of its very nature the degrees of traumatic occlusion are difficult to describe, as the distinctions are so fine as to be comparable to a minute degree of shading in color. Adjustment of occlusion may so alter the movements of the mandible as to enhance the symmetrical evolution of the face.

Habits may be an etiologic factor in periodontal disease and should be carefully noted and corrected. Dysfunction from non-occlusion may be a contributing cause also. The establishment of healthy circulation by passive massage is of paramount importance in such cases as the increased blood supply from massage raises the resistance of the tissue to disease. Orthodontia and restorative procedures may be required. In the case of migrating teeth first the cause must be removed then they must be restored to their proper functional position.

Necrotic gingivitis is 'a painful inflammation of the gingival tissues characterized by a type of pseudomembranous formation (made up of bacteria and necrotic tissue) and superficial ulceration'. A differential diagnosis should be made to give proper treatment as various diseases have been traced to the associated organisms. Experiments have been made with sulfonamide compounds and results with their local application appear promising. Other drugs and their application are described at length. Diet has a direct relationship to dental and periodontal disease. Leading nutritionists use the oral changes for determining deficiencies of vitamins as well as the efficiency of vitamin therapy. The mouth is the zone of greatest susceptibility and its structures are most accessible for observation making it the ideal place to find early and advanced lesions not only of nutritional deficiencies but of many systemic diseases before they become apparent through other symptoms.

The endocrine system is presented in its relation to dental health as well as to systemic disturbances. In hypothyroidism dentition is retarded and teeth erupt in the wrong sequence and are poorly calcified. In hyperpituitarism teeth are found to erupt prematurely and to be too widely spaced. Metabolic disorders are not always manifestations of pathologic conditions since they may also represent evidences of self healing. Periodontitis and diabetes are interrelated. Lintz assumes that local infection is frequently the cause of diabetes. Sugar percentage has shown lower value after periodontic treatment. The medical practitioner should work in close cooperation with the dentist in the treatment of systemic diseases related to periodontal disturbances.

Education of the public to the value and necessity of periodontal treatment will require patience as the idea that pyorrhea is an incurable disease has been too firmly established. Miracles cannot be performed if the disease has gone so far that the tissue around the tooth has been nearly destroyed leaving the member without support of any kind in a mass of 'labby tissue.'

But when the cause is discovered in time and the proper remedy is applied, the tightening of the teeth borders on the miraculous. The method of presenting the benefits of periodontal treatment necessarily varies, according to individual eccentricities. Slides, models, photographs and verbal and printed comments find their place in this missionary work. In periodontia the patient must be kept constantly aware and constantly interested in his part of home care, tooth brushing technic and alterations in diet to obtain lasting results. The dentist then should clearly define his reasons for reconstructing bridges, if necessary, and replacing missing teeth to establish a balanced occlusion.

Proteins, Amino Acids and Peptides as Ions and Dipolar Ions. By Edwin J. Cohn and John T. Edsall. Including Chapters by John G. Kirkwood, Hans Mueller, J. L. Oneley and George Seastard. American Chemical Society Monograph Series. Cloth. Price, \$13.50. Pp. 686 with illustrations. New York: Reinhold Publishing Corporation, 1943.

This book is not a systematic treatise on the chemistry of amino acids, peptides and proteins or even on the physical chemistry of these important substances. It deals with them from the limited point of view of the number and distribution of the electrical charges they bear and the "implications of their charged structure for their physical properties and their physicochemical interaction with other molecules." The field covered by the monograph was opened by the studies of Debye and Huckel on the interionic forces in electrolyte solutions and by the work of Bjerrum, who demonstrated that aliphatic amino acids, even in the isoelectric state, bear positively and negatively charged ionic groups, by virtue of which they react as zwitterions, or dipolar ions. By applying these fundamental concepts to theoretical and experimental studies of amino acids, peptides and proteins, the authors and their associates have paved the way to new and fruitful methods of protein investigation. This book is therefore the result of years of discussion and collaboration by a number of leading workers in this field. It is divided into two parts: part 1 on amino acids and peptides, part 2 on the size, shape and electric charge of protein molecules. Individual chapters in the book have been contributed in general by individual authors. The nature of the subject is such that this is not an easy book to read. It is, however, a book which will repay the serious student of the subject by giving him a deeper understanding of the structure and reactions of protein molecules and of their importance in living cells. The more casual reader will find it invaluable as a work of reference in this rapidly developing field.

Physiological Regulations. By Edward F. Adolph, Associate Professor of Physiology in the University of Rochester, Rochester, New York. Cloth. Price, \$7.50. Pp. 502, with 186 illustrations. Lancaster, Pennsylvania: Jaques Cattell Press, 1943.

"Animals preserve their constitutions and activities like themselves, within the limits of variation that characterize the normal, either by preventing disturbances from occurring, or by compensating for each actual and incipient departure from normal" (p. 479). Summarized with that statement, this monograph represents a quantitative study of the restoration of physiologic equilibrium after its disturbance. Drawing freely on published work from his own and other laboratories, while presenting also appropriate hitherto unpublished data, the author mathematically characterizes recovery from increments or decrements ("loads") of components such as water or heat. Relationships between variables are portrayed graphically, using, in many instances, quotients and coefficients in order to increase the number of variables represented on a single pair of axes. Chapters and sections are provided with valuable summaries, and the last chapter contains recapitulations that may be read with profit before one approaches the more specific and detailed presentations of experimental data.

On casual inspection the title of the book appears to be misleading because of the many pages of text devoted solely to the subject of water exchange. More careful examination reveals, however, that a quantitative description of water exchange is used as an introduction to the study of a variety of types of regulation, including heat, "total substance," dextrose, carbon dioxide, oxygen and lactic acid. Although the book as a whole is written in an impersonal first person, here and there one encounters passages which intimately disclose the likes and dislikes, favors and prejudices of the author. Appar-

ently anticipating criticism of his having selected a descriptive method of research, the author includes also a defense of that method in which he justifies his use of quantitative description.

Endocrinologists and neurophysiologists may not agree with the concept that regulation is "a generalized statement of uniformities of relations among [phenomena]" (p. 451). Little attention is given to the role of specialized cells in the maintenance of balances. For example there is no comprehensive discussion of the activity of the supraoptico-hypophyseal system in water equilibration or of the function of the hypothalamus in the regulation of body temperature. But the study does not pretend to exhaust the possible interrelations of physiologic variables. Since the experimental method here utilized can be applied not only to description of the behavior of the whole organism but also to study of its parts, there remains an opportunity for a similar investigation of the function of "regulatory mechanisms" composed of specialized cells of the nervous system or the endocrine glands.

Mind, Medicine and Man. By Gregory Zilboorg, M.D. With a foreword by Arthur H. Ruggles, M.D. Cloth. Price, \$3.50. Pp. 344. New York: Harcourt, Brace and Company, 1943.

The author is engaged in private practice in psychiatry and psychoanalysis in New York. With George W. Henry he has written a history of medical psychology which has been well received. The chapter headings indicate the nature as well as the wealth of the material in the present book on certain misconceptions, instincts and their manifestations, normal neuroses and personality, certain aspects of mental illness, theories and practice, civilization and social sciences, varieties of human aggression, crime and judgment, psyche, soul and religion. The discussions are able, scholarly and comprehensive, leading the way to better understanding of psychiatric problems. In his foreword Dr. Ruggles writes "How fortunate it is that in these days of disordered thinking, feeling and acting we have a pathfinder who so ably helps us in correcting psychological misconceptions." The book has a special appeal to those who are interested in the advances of knowledge of the human mind—churchmen, lawyers, scientists, physicians.

Brucellosis in Man and Animals. By I. Forest Huddleson, D.V.M., M.S., Ph.D., Research Professor in Bacteriology, Michigan State College, East Lansing. Contributing Authors: A. V. Hardy, M.S., M.D., Dr. P.H., Associate Professor of Epidemiology, DeLamar Institute of Public Health, Columbia University Medical School, New York; J. E. Debono, M.D., M.R.C.P., Professor of Pharmacology and Therapeutics, Royal University of Malta; and Ward Giltner, D.V.M., M.S., Dr. P.H., Dean of Veterinary Division and Professor of Bacteriology, Michigan State College, East Lansing. Second edition. Cloth. Price, \$3.50. Pp. 379, with 43 illustrations. New York: Commonwealth Fund, 1943.

Brucellosis has assumed a place in medicine of worldwide importance. It is only proper, therefore, that in the revised edition of this book Dr. Huddleson should supplement his extensive observations on the disease in animals with the experience of physicians on the disease in human beings both in this country and in Europe. Dr. J. E. Debono of the Royal University of Malta presents a discussion compiled on the large number of cases that have occurred on that island, while Dr. A. V. Hardy surveys the ramifications of the disease as found in the United States. The clinician, the pathologist and the epidemiologist will find detailed and specific recommendations in the material. Numerous case reports appear in the appendix that should be of service to the physician. The control of the sources of brucellosis infection is discussed by Dr. Ward Giltner with emphasis on the area eradication program for cattle. Sheep, goats and hogs present a lesser problem in the United States.

Patología funcional de la glándula mamaria. Las mastopatías hormonales. Por Antonio Egües. Paper. Pp. 190 with 17 illustrations. Buenos Aires, 1942.

This is a complete review of the long debated topic of precancerous changes of the mammary gland and on the Reclus or Schimmelbusch's disease, the author contributing numerous personal cases. It is concluded that a precancerous condition can be feared only when the evolution of a cystic mammary tissue is toward papillomatous formation and not toward simple atrophy. The study is purely clinical, no mention being made of the important contributions from workers on the same problem in rabbits and mice.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE ANSWERED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THIS WILL BE OMITTED ON REQUEST.

FLAT FEET SPASM AND MUSCULAR ATROPHY

To the Editor—A boy aged 3 has had flat feet since birth and walks with a humped gait (dragging the right leg much like a hemiplegic). He has atrophy of the right leg which measures about an inch smaller than the opposite one in all dimensions. There is no shortening. Can flat feet cause atrophy of either extremity and if so how?

C. H. Whiting, M.D., New York

ANSWER—This is an interesting question. First to answer the question as to whether flat feet can cause atrophy of either extremity, yes, it can. Flat feet can occur with atrophy and may be associated with muscle spasm either in only one foot or in both. Since the spasm is a physiologic reaction to prolonged strain, a muscle spasm of this type would give a hemiplegic like drag of the leg. The probability is that the boy has flat feet with a functional compensation meaning, that he has flat feet but the feet are not strong enough to do normal work. Therefore spasm may develop and he may have a dragging foot like a hemiplegic.

Treatment should consist in correction of the flat feet by bringing the heel into varus and correction of the supination of the anterior part of the foot that is bringing the head of the first metatarsal bone plantarward. In this way the arches can be reestablished. By holding this position and using the feet in normal exercise such as normal walking it is possible ultimately to change the position of the feet.

SEVERE LANCINATING PAINS

To the Editor—A man aged 50 has been suffering from intermittent attacks of idiopathic lancinating pain for twenty years. The pains are sudden or gradual in onset, localized anywhere on the body at different times, last for variable periods of time from a few minutes to hours and may come in groups of pains for a few hours to a few days. The patient has had syphilis and was treated for it repeatedly but irregularly. He has just completed a course of antisyphilitic treatment and his Wassermann reaction is negative. He had the pains before and after this treatment and there has been no noticeable change from the treatment. Visits by literally at least two dozen doctors in the United States and in Puerto Rico have failed to relieve him. All other studies have been normal including blood sugar, urea, protein, nitrogen, uric acid, basal metabolic rate, urinalysis, calcium, phosphorus, spinal fluid, neurologic studies and stool examination. There is no history of alcoholism or heavy metal poisoning or avitaminosis. His picture does not fit in with any diagnosis suggested by neuritis in Barton and Yater's Symptom Diagnosis. There is no muscle weakness or any cutaneous evidence of a pathologic condition at any time. It is not affected by weather. The nearest I could come to a diagnosis was idiopathic neuritis and since no other treatment which had consisted of salicylates, calcichone, vitamins of every nature, low protein diet, analgesics and arsenicals had helped him, I tried a dose of intramuscular pitressin on the theory that herpes zoster was sometimes helped by pituitary extracts and that even if he didn't have herpes it might be a variation of it. Miraculously his pains disappeared for a month which was the longest time they had ever gone. Then the pains returned the same as ever. Another dose of pitressin caused a good bowel movement immediately disappearance of the pains for ten minutes recurrence for twelve hours and then disappearance for two weeks which is the present time and the pains have not returned yet. Please help me relieve this perennial sufferer.

M.D., Puerto Rico

ANSWER—The description given of the patient's "pains" is quite typical of the lightning pains of tabes dorsalis but patients with such involvement usually show some objective evidence of syphilitic involvement of the central nervous system such as pupillary changes, decrease or increase in deep reflexes, or sensory changes.

In about 15 per cent of the tabetic in whom the spinal fluid has become negative the lightning pains will persist. In many of these patients the "arrest" of the disease may occur spontaneously, without the benefit of antisyphilitic therapy. Neither does treatment with arsenic, bismuth, mercury or iodides offer these individuals relief from the pain after the spinal fluid has become negative. Fever therapy is likewise disappointing but an occasional patient obtains relief from the use of thiamine hydrochloride in large doses such as 100 mg by hypodermic once a day for thirty or more injections. Exposure to cold, barometric changes, fatigue and nervous exhaustion, excess of protein or sugar in the diet, focal infections and infected urinary bladders are some of the factors that these patients have reported as increasing their pain.

It is difficult to prevent such patients who derive no benefit from the medications mentioned or similar drugs from becoming morphine habitues. Neither is it possible to assure them that time will anchorate their pain, because in the majority the pains persist indefinitely.

VALUE OF URINARY ALBUMIN AND CASTS IN DIAGNOSIS OF NEPHRITIS

To the Editor—I am clinical pathologist for an army induction team. We are having difficulty in knowing when to reject a man with albuminuria. The U. S. Army defines nephritis as persistent albuminuria with or without casts. The Army routine is this: "Whenever a man shows albumin (regardless of microscopic findings) urine is immediately repeated, even five or six times in one day." If a urine becomes normal it is called a transient albuminuria and the man is accepted. I myself feel that if one sample shows casts there is renal disease. I also feel that even with nephritis not every sample will be abnormal. If urine persistently shows albumin throughout one day the inductee is held over and reexamined the following day. If several samples still show albumin the same thing is done on the third day and sometimes even on the fourth but as soon as an albumin free urine appears he is accepted. Do you think albumin should be called transient under these conditions? Do you think we would be justified in postponing examination for an interval say of one month after even one albuminuria even without casts?

M.D., New York

ANSWER—In answer to the first question it is just as much an error to assume that the kidneys are normal because one urine sample out of five is negative for protein as to assume that there is kidney disease because one urine sample out of five is positive for protein. Several factors determine whether the test for proteinuria is positive or negative—sensitivity of the test, the amount of electrolytes in the urine, the reaction, and especially the dilution or concentration of the particular sample.

It is not entirely correct to assume renal disease because of the presence of casts in one sample unless one takes into account the number and nature of the casts. A few hyaline casts may have no significance whereas one red cell, epithelial cast or fatty cast may mean serious renal disease. The effects of exercise, exposure to cold, posture and acid-forming salts must be considered in interpreting the finding of a few casts.

It is quite true that even in nephritis not every sample of urine will be abnormal if the specimens are obtained under ordinary conditions. However, it is rare to fail to find albumin casts or excessive red cells and white cells in a concentrated acid urine obtained as a result of deliberate dehydration or the patient. No diagnosis of the presence or absence of nephritis should be made without the examination of such a urine specimen.

In the case of the inductee who is held over for several days until he can produce a urine sample free from albumin, the underlying assumption seems to be that the original positive tests were due to extraneous or extrarenal factors. This is a risky assumption unless a more thorough investigation of the cause of the original albuminuria is undertaken. Postponing the examination for a given interval would not clarify this situation because the same condition that produced "transient" albuminuria on the first examination may do so again. The proper procedure is to obtain as concentrated a urine as possible by keeping the subject on a dry diet for twelve to twenty-four hours, and examining this urine for specific gravity, protein and sediment.

If a concentrated and acid urine sample cannot be obtained the inductee should be held over until such is produced or until other studies such as blood chemistry and intravenous pyelography furnish sufficient normal or abnormal findings to settle the question of renal disease.

IMMUNIZATION AGAINST TETANUS

To the Editor—Can you tell me whether or not there have been any fatalities in the United States Army from immunization against tetanus? I write this because some army officer (not medical) has been telling patients of mine that 600 soldiers have died from these injections and I am anxious to refute this type of rumor immediately and authoritatively.

Don Tucker Miller, M.D., St. Louis.

ANSWER—It is apparent that some one has been grossly misinformed concerning reactions and fatalities from the administration of tetanus toxoid. True in the early part of the tetanus immunization program some reactions or sensitivity to the toxoid were experienced. It was learned soon that the great majority of these reactions were resulting from sensitivity to certain peptone components of the toxoids in use at that time. These peptones have not been used in making tetanus toxoid for use by the Army since the late summer of 1941. Since that time several million doses of tetanus toxoid have been

administered and the reports of reactions of sensitivity received have been so few as to be practically negligible.

This subject was covered in some detail in an article published by one of the officers in the Preventive Medicine Division of the Office of the Surgeon General in the *American Journal of Public Health*, January 1943. The title of this article is "Tetanus Toxoid, Its Use in the United States Army." An estimate was given in that report of the frequency of reactions of sensitivity, and this frequency was considered to be somewhat less than 1 in 10,000 injections. While exact figures are not available, the incidence of these reactions is in all likelihood considerably less than 1 in 50,000 injections.

There is no truth in the allegation that 600 soldiers have died from injections of immunizations against tetanus. The fact is that the occasional reactions that do occur are for the most part extremely mild and are characterized by nothing more alarming than a generalized urticaria.

PSEUDOANGINA AND CONSTIPATION AS SYMPTOMS OF PROBABLE NEUROSIS

To the Editor—For the past two years I have been treating a white woman aged 41. She has a history that started nine years ago when she fell the street while walking. She fell on her abdomen with great force. A few weeks after this, while she was walking with her husband, he was suddenly seized with a fatal coronary occlusion. Soon after this the patient began complaining of precordial pains. The attending physician felt that this was nervous in origin and prescribed sedatives. Two months after her original fall she began complaining of epigastric pain, severe pain immediately after every bowel movement and pain in the precordium. This syndrome has defied diagnosis on an organic basis. The patient suffers severely from constipation and despite every known method of therapy she cannot move her bowels oftener than once every four to six days and only then with a saline cathartic. In the past three months she has lost about 10 pounds (4.5 Kg.), and this has been the most aggravating part of her illness because now she is convinced that she is severely ill. I might add that she was married again about one year ago to a kind and thoughtful man, but he is impotent in that he cannot maintain an erection and therefore they have never had intercourse. The patient is neat, extremely pretty and of fine character. The family history is negative. She weighs 127 pounds (57.6 Kg.) nude. There is not a single positive clinical finding, aside from a midline abdominal scar, the result of an appendectomy. She has had a thorough workup, including an electrocardiogram, an x-ray examination of the chest, gastrointestinal and gallbladder series, complete blood count, blood sugar and urea nitrogen, urinalysis, stool culture and study for blood, special x-ray studies for possible diaphragmatic hernia, psychiatric examination, Wassermann test and a basal metabolic test. All these have been found normal. The psychiatrist believes that she has neurosthenea. I have talked with the patient for hours and despite everything she still has her pains and her constipation. Can you help me?

M D, New York

ANSWER—Pseudoangina is a common disease of nervous persons, and especially of persons who have watched a loved relative dying of heart disease. This woman had enough of a psychic shock to produce a neurosis, and a common symptom of neurosis is pain.

Pain right after defecation in a nervous, hypersensitive woman is practically always of functional origin. It is an exaggeration of the distress and weakness some persons feel after a large diarrhetic bowel movement. Such patients generally do best if permitted to stay constipated. Some take an enema once every four or five days. A half hour before taking the enema, they may take a dose of bromide to dull the distress that will follow the bowel movement.

Often, if sufficiently reassured, these patients will endure the pain without much more complaint. The husband's impotence may well be a factor in keeping up the distress. If this is true, the woman must be told to expect no improvement until she makes up her mind definitely either to stay in her bed and acquiesce to the situation or else to get out and ask for an annulment.

COARCTATION OF AORTA

To the Editor—I should appreciate knowing something of the history of coarctation of the aorta. Who first described the condition and when? When the clinical and roentgenologic findings are observed in an adult with a history of no previous symptoms or signs, can this be construed as an acquired form of stenosis of the aorta rather than a congenital anomaly?

M D, South Dakota

ANSWER—Coarctation of the aorta has been well known for more than a hundred years. Early cases were reported by Paris in 1791, Sir Astley Cooper in 1818, Otto in 1824 and Laennec in 1826. As a matter of fact the case of greatest longevity (92 years) on record was reported as long ago as 1828 by A. Reynaud. The collateral circulation in coarctation of the aorta was well described by Meckel in 1827 and by Jordan in 1830. Bonnet in 1903 divided coarctation into the two types (1) infantile, which is the serious short lived type, and (2) adult, which is the ordinary clinical type, which can be usually readily diagnosed in childhood and middle age.

The clinical and roentgenologic findings in coarctation of the aorta discovered in an adult with a history of no previous symptoms or signs are to be construed as evidence that coarctation of the aorta developing at birth had been present all along but previously missed. So far as is known, it is not acquired later on in childhood or adult life. It is not rare for these cases to be overlooked for many years, and this fact is one of the reasons why it should be thought of and looked for in any young person with unexplained hypertension.

CHRONIC TRACHEAL AND BRONCHIAL IRRITATION

To the Editor—Patients with chronic hemolytic streptococcus bronchitis with cough and expectoration constitute my problem. All studies, including the tuberculin skin test, x-ray and bronchoscopy in some, have been negative except persistent cultures of beta hemolytic streptococci. Various remedies have been tried, including sulfonamide drugs, without any apparent benefit. Is there any specific therapy of value in these cases aside from the general upbuilding of the patient? Stock and autogenous vaccines have apparently been without benefit.

M D, New York

ANSWER—The persistent hemolytic streptococci in such cases may or may not be the actual cause of the condition. These bacteria more often cause acute rather than chronic infections. Unless they are constantly present in great predominance over other varieties, it is probable that they are saprophytes in the cases referred to. If they are, it is not surprising that the sulfonamide compounds had no effect in treatment. There is of course, no logical basis for the use of specific vaccine therapy of any kind. However, beneficial effects sometimes follow the nonspecific reactions which may be provoked by vaccines. There is therefore no specific therapy available at present to recommend for these patients. The questioner is probably correct in suggesting general upbuilding of the patient. Perhaps a change in climate may be helpful. Inquiry should also be made into the amount of smoking or talking the patient does. Patients often cough unnecessarily hard or too frequently, which may in itself aggravate and perpetuate laryngotracheobronchial irritation. Inhalations of plain or slightly medicated steam, or spraying a 0.5 per cent solution of mono-p-chlorophenol in liquid petrolatum deeply into the trachea once or twice daily for a short time often alleviate cough.

MALARIA IN ALABAMA

To the Editor—How common is malaria in southern Alabama? What are the chances of one's contracting malaria in moving from the North to a gulf town in Alabama?

M D, Florida

ANSWER—Malaria in southern Alabama is endemic, and among the more susceptible groups of individuals it is quite common to find typical and even virulent cases.

By far the greater number of cases, however, are chronic. The symptoms are atypical (afebrile generally) and as a rule parasites are not demonstrable in the blood and, if demonstrated, are scanty in number and low in virulence.

The chances of contracting the disease by unacclimated persons would be great. This applies particularly to the coastal regions and river valleys and to those who fail to take reasonable precautions by screening after nightfall.

SMALLPOX REVACCINATION AFTER POSTVACCINAL ENCEPHALITIS

To the Editor—At the age of 7 a patient of mine suffered a postvaccinal encephalitis and was desperately ill for several days. She recovered completely, has done well in school and college and has a pleasing personality. She now wishes to join the Waves and consulted me to ask if there was any reason why she should not be revaccinated, which is, of course, required in the service. I have been unable to find any reference to this in the medical literature. Can you tell whether there is any danger entailed in revaccinating the patient, who is now 20 years old?

Warren Ripley, M D, Montclair, N J

ANSWER—References dealing specifically with this question have not been found. There are, however, a number of articles which quite clearly indicate that the risk of revaccination to a young woman who suffered postvaccinal encephalitis many years ago would be so slight as to be insignificant. Gordon and Rhea (*Postvaccinal Encephalitis*, *Am J Hyg Sc* 184:104 [July] 1932) say that "postvaccinal encephalitis is essentially a disease following primary vaccination of patients between 6 and 11 years of age." Scott (*Postvaccinal Encephalitis in Infancy*, *Brit J Child Dis* 27:245 [Oct-Dec] 1930) says: "Immunity or even partial immunity to vaccination appears to carry with it an immunity to postvaccinal encephalitis. No case of encephalitis has occurred in a negative take, and after revaccination the condition is extremely rare."

DL-GLUTAMIC ACID HYDROCHLORIDE IN TREATMENT OF PETIT MAL AND PSYCHOMOTOR SEIZURES

J. C. PRICE, MD

H. WAELSCH, MD, PhD

AND

T. J. PUTNAM, MD

NEW YORK

In the majority of cases the treatment of epilepsy is moderately satisfactory.¹ Grand mal attacks are controlled completely or reduced in frequency by phenytoin or phenytoin-phenobarbital combinations in the majority of cases. Psychomotor attacks yield less readily to anticonvulsant therapy. Petit mal attacks are infrequently affected by medication but respond favorably to fasting² and the ketogenic diet.³

The hypothesis advanced by Wilder³ and supported by Keith's experiments⁴ that the mechanism of the ketogenic diet depended on the sedative effect of the ketone bodies was not generally accepted. Fay⁵ and McQuarrie⁶ attributed the effect to dehydration incidental to ketosis. Bridge and Iob⁷ were doubtful that either to acidosis or to ketosis alone could be ascribed anticonvulsant properties.

Maintenance of a dietary regimen that will produce ketonuria is not a simple task. Hospitalization and an intensive educational program for the patient and his

parents are necessary. A search for acidosis producing drugs was the outgrowth of these disadvantages of the ketogenic dietary regimen. We have used ammonium chloride (2 cases included in this series) without striking results. Azosulfamide⁸ reduced the frequency of seizures moderately and concomitantly lowered the pH of the blood. Brilliant vital red also seemed to have a moderate anticonvulsant effect.⁹

Putnam and Merritt¹⁰ suggested that the "physiologic" anticonvulsants dextrose, carbon dioxide, pyruvic acid and acetoacetic acid and the synthetic anticonvulsants produce their effect by giving rise to an acid milieu within or about nerve cells. The synthetic anticonvulsants are of a composition which suggests that they are broken down by cellular activity, perhaps chiefly in the brain, to stable acid products such as benzoic acid. Anticonvulsant treatment of epilepsy is suggested as a substitution rather than drug therapy.

The use of *DL*-glutamic acid was suggested by one of us (H. W.) on the basis of the following considerations:

It is known that some racemic amino acids, among them *DL*-glutamic acid, give rise to the excretion of the unnatural isomer in the urine when administered to animals. If *D*-glutamic acid has a similar metabolic inertia¹¹ in human metabolism, 1 mole of *D*-glutamic acid hydrochloride should furnish 1 mole of hydrochloric acid and two carboxyl groups of which one would be available for acidification. The *L*-glutamic acid hydrochloride also furnishes one equivalent of hydrochloric acid.

Furthermore, *L*-glutamic acid has been stated to be intimately related to brain metabolism. It is the only amino acid known to be metabolized by slices of brain tissue.¹² Brain tissue contains an enzyme which synthesizes glutamine from *L*-glutamic acid and ammonia, decreasing by this mechanism the concentration of free ammonia in the tissue.¹³

Patients with seizures usually associated with slow wave activity in the electroencephalogram were selected for treatment. The amount of the amino acid hydrochloride required to maintain the pH of the urine at about 5.0 was 4 Gm. three times a day. Larger doses

Read before the American Psychiatric Association, Detroit, May 10, 1943.

16 and 20 Gm, were administered in 2 cases. Oral administration of the drug in dilute solution or capsules was seldom associated with gastric distress. Anti-convulsant therapy, though ineffective, was continued throughout the trial period.

Nitrazine paper tests of the morning specimen of urine were made by the patient in the majority of instances. This test gives the relative degree of acidity within half a pH unit approximately. The *dl*-glutamic acid hydrochloride was prepared by one of us (H. W.).

REPORT OF CASES

CASE 1—K. Mac, aged 12 years, had had petit mal seizures which recurred at a frequency of about forty to fifty a day for four years. A six months trial of the ketogenic diet reduced the seizures moderately. The patient refused to continue the rigid regimen.

General physical and neurologic examinations were within normal limits. Negative laboratory tests included a complete blood count, urinalysis, a blood Kline test, psychometric studies and x-ray examination of the skull. Frequent petit mal seizures were accompanied by typical three per second wave and spike formations in all leads of the electroencephalogram.

Maximum tolerated doses of phenytoin sodium and phenobarbital reduced the seizures slightly, that is, the number of days on which fifty seizures occurred were reduced. *dl*-Glutamic acid hydrochloride administration was accompanied by a sharp decrease in seizures. The dose required to maintain a urinary pH of about 5.0 was 12 Gm daily. Attacks were reduced to about five to twenty-five a day in contrast to twenty-five to fifty.

In addition to the reduction in seizures, the patient's parents and instructors in school noted a decided improvement in the patient's personality. He accepted disciplinary measures without prolonged arguments. He was more congenial, cooperative and affable. Peculiar egocentric aptitudes were decreased. Concentration and application in his school work were improved.

Ammonium chloride (40 Gm daily) administered for five weeks failed to influence the frequency or severity of seizures.

In this case *dl*-glutamic acid hydrochloride reduced the total number of seizures and produced an improved physical and mental alertness pleasing to patient, parents and other interested parties. Ammonium chloride proved ineffective.

CASE 2—M. B., aged 13 years, had had petit mal seizures (fifteen to thirty daily) for three to four months. Mild depressions were noted occasionally as a result of the recurrent seizures. General physical and neurologic examinations gave negative results. Negative laboratory examinations included a blood count, urinalysis, a blood Kline test, an x-ray examination of the skull, a pneumoencephalogram and psychometric studies. The electroencephalogram showed a pattern commonly associated with convulsive disorders, petit mal type.

Phenytoin sodium and phenobarbital therapy was ineffective. *dl*-Glutamic acid hydrochloride reduced the number of seizures to two to five a day. The pH of the urine was lowered to 5.0 in forty-eight hours and maintained at this level. The decrease in frequency of the seizures paralleled the lower pH values of the urine.

The ingestion of the drug was accompanied by an immediate improvement in the clinical condition of the patient. In the past nine months the drug has repeatedly been discontinued with the result that the symptoms have immediately recurred. Improvement has followed readministration of the drug in adequate doses.

The decrease in seizures was accompanied by an improved mental and physical alertness. Exacerbation and remissions of symptoms were closely correlated with glutamic acid therapy.

CASE 3—C. H., aged 7 years, had recurrent petit mal seizures which had resisted phenytoin sodium, phenobarbital and a combination phenytoin-phenobarbital therapy. General physical and neurologic examinations gave negative results. Negative

laboratory examinations included x-ray examinations of the skull, psychometric studies, urinalysis, a blood count and a blood Kline test. The electroencephalogram revealed a pattern commonly associated with convulsive disorder, petit mal type.

Following the determination of tolerant doses of phenytoin sodium and phenobarbital, *dl*-glutamic acid hydrochloride was administered. The drug in concentrated solution caused severe gastric distress. He later rejected dilute solution (in water, milk, fruit juices). During this period of inadequate treatment petit mal seizures increased from six to ten to twenty to twenty-five a day.

This is the lone instance of severe gastric distress caused by the drug. Obviously the concentrated solution caused the gastric discomfort. The increased frequency of seizures was related to the emotional response rather than to the effect of the drug. Petit mal seizures are often increased in frequency and severity by excitement, worry, stress and strain.

CASE 4—S. K., a girl aged 8 years, had a recurrent abdominal pain which was first noted at the age of 6 years. Acute pain followed by vomiting recurred weekly for four months. The recurrence of pain ceased, but frequent short periods of staring were noted by the parents. Subsequently this symptom was accompanied by right sided signs (facial asymmetry, clonic movements of the right hand and face and a tendency to fall to the right). Though predominantly on the right, seizures have been noted to occur on the left side for periods of as long as two weeks. The frequency of seizures varied from one hundred to two hundred a day. Personality disturbances (disobedience, destructiveness, cruelty to her playmates and indifference) were not related to the frequency of seizures or medication and responded readily to the use of customary disciplinary measures.

Pneumoencephalograms have been normal on three occasions. Psychometric studies disclose an average intelligence (intelligence quotient 101 Stanford-Binet, 114 Arthur). The electroencephalogram repeatedly demonstrated a focus of slow wave activity in the left temporoparietal area.

Right facial weakness and impairment of motor function, voluntary and involuntary, in the right arm and leg has progressed slowly. She is now unable to write with her right hand.

Various combinations of phenytoin sodium, phenobarbital, thyroid, *dl*-pyrrolidone carboxylic acid and *dl*-glutamic acid hydrochloride, ammonium chloride, ketogenic diet, nicotinic acid and methyl ethyl phenobarbital were administered. Phenobarbital in increasing dosage to 0.3 Gm daily was moderately effective over the longest period of time any one drug was administered. *dl*-Glutamic acid hydrochloride in combination with phenobarbital was strikingly effective. Except for an increase in the number of seizures accompanying the excitement of going home, the greatest number of days on which twenty-five seizures or less could be counted was noted within the ensuing two months. Five seizures or less were noted for two consecutive weeks. Seizures recurred at the pretreatment frequency immediately after withdrawal of the drug. Renewal of treatment was not accompanied by a decrease in frequency of the attacks, but this fact is difficult to evaluate because thyroid in toxic doses was administered during the second trial period.

Methyl ethyl phenobarbital in conjunction with nicotinic acid and phenytoin sodium was also accompanied by a striking improvement. Initially the seizures decreased in severity and later in frequency. For two months from one to ten seizures occurred daily, accompanied by a moderate return of function of the right hand. Unavoidably methyl ethyl phenobarbital was discontinued, and the seizures immediately recurred.

On readmission to the hospital, right sided seizures recurred at intervals of five to fifteen minutes.

Evaluation of medication is difficult, but we were impressed with the response accompanying *dl*-glutamic acid hydrochloride therapy, in conjunction with phenobarbital.

CASE 5—J. R., a youth aged 21, had recurrent psychomotor seizures preceded for an hour of repeated myoclonic twitches and mental confusion which were decreased by phenytoin sodium, phenobarbital and thyroid.

General physical and neurologic examinations were negative. Negative laboratory examinations included a complete blood count, urinalysis, x-ray examinations of the skull, pneumoencephalogram, psychometric studies and blood Kline and sugar tolerance tests. The basal metabolic rate was minus 18 mm, -22 and minus 20 and serum cholesterol was 271 mg per hundred cubic centimeters. The electroencephalogram showed a pattern commonly associated with convulsive disorders.

Seizures recurred at weekly intervals without treatment. Administration of phenytoin sodium, phenobarbital and thyroid in maximum tolerated doses was accompanied by a reduction in seizures, namely one attack every one to three weeks. Extra phenytoin sodium and phenobarbital administered after the onset of the aura had no effect on the impending seizures.

Ammonium chloride (4 to 6 Gm daily) reduced the frequency of seizures slightly, but the appearance of severe acne prevented its prolonged administration.

After addition of *dl*-glutamic acid hydrochloride to the foregoing combination seizures could be prevented by the use of phenytoin sodium (0.1 Gm) and phenobarbital (0.1 Gm) during the phase of the aura. Attacks were prevented for a period of three months, the longest inter-seizure interval in two years.

The dosage required to maintain a urinary *pu* of 4.5 to 5.0 was 12 to 20 Gm.

Equally encouraging was the subjective improvement. Parents, friends and business associates volunteered the information that the patient's behavior had changed for the better. He was decidedly more affable. His gymnasium instructor reported an improved physical alertness. His assistant noted an increased mental acuity. For the first time he desired and sought social contacts outside the family circle. Hospital attendants noted a decided improvement in cooperation in respect to both hospital routine and clinical tests.

In this case decided psychologic improvement followed an increased mental and physical alertness which has aided measurably in social and economic rehabilitation. Seizures recurred at one to four week intervals following withdrawal of the drug irrespective of supplementary medication after the onset of the aura. Though the major portion of the psychologic improvement has been maintained, there has been no progress on other forms of medication.

A regimen designed to determine the effect of *dl*-glutamic acid hydrochloride on the acid-base balance of the blood has recently been instituted. Twelve Gm doses of the drug have failed to alter the acid-base balance and likewise to affect the frequency of seizures. Failure to respond is probably associated with an intake of excessive doses of thyroid, as in case 4. Symptoms of thyroid intoxication (weakness, sweating, fatigue, restlessness and emotional lability) have been noted recently. After thyroid was discontinued the favorable response to glutamic acid has been reproduced.

Even though seizures may be aborted by supplementary therapy after the onset of the aura the latter occurs more frequently during the period of *dl*-glutamic acid hydrochloride therapy. The aura is associated with the fast activity and the psychomotor seizures with slow wave activity in the electroencephalogram. This suggests that the drug is effective only in seizures associated with slow wave activity. Improved mental and physical alertness have aided measurably in social and economic rehabilitation.

CASE 6—B. J., a man aged 25, had a moderately severe head injury at the age of 3 years; this was the only suggestion of an etiologic factor disclosed in the history. Unlike his brother and sister, the patient had always been irritable, restless, emotionally labile (temper tantrums, indifference, depressions) and retarded mentally (school work difficult and far below standards of the family). Anxiety states resulting from recurrent periods of mental dullness prevented employment. He

resented his mother's habit of repeatedly recounting his inadequacies to him and others. Though he honestly attempted to maintain employment, recurrent grand mal, petit mal, psychic equivalents and periods of mental dullness prevented contact with the public.

Hemiatrophy of the left arm and leg suggested the presence of diffuse involvement of the right hemisphere of the brain, probably post-traumatic in origin. Confirmation of this opinion was demonstrated in the electroencephalogram, namely a diffuse abnormal pattern was most severe in the right frontal area.

Except for psychic equivalents and periods of mental dullness the patient has been symptom free with phenytoin sodium (0.4 Gm) and phenobarbital (0.1 Gm) therapy.

dl-Glutamic acid hydrochloride was administered in 12 Gm doses daily. Objectively the psychic equivalents and periods of mental dullness were unaffected. Subjectively interseizure periods were accompanied by an increased mental and physical alertness new to the patient. Though not dramatic, the effect was definitely encouraging to him. The drug was discontinued suddenly six weeks later, following which symptoms were intensified and a grand mal seizure occurred, the first in seven months. Readministration of the drug was accompanied by an improvement similar to the previous one. Exacerbation of the symptoms again followed interruption of treatment four weeks later.

In this case subjective improvement accompanied ingestion of *dl*-glutamic acid hydrochloride. Interruption of treatment was followed by an exacerbation of symptoms and improvement occurred on reinstitution of therapy. Exacerbation of symptoms commonly associated with irregular inadequate treatment of epilepsy is exemplified in this case.

CASE 7—M. B. S., a woman aged 41, had onset of seizures at the age of 20. Severe social, educational and economic restrictions have been a serious handicap. Seizures were strikingly reduced by phenytoin sodium. Personality disturbances combined with social maladjustment prevented a satisfactory rehabilitation following control of the seizures. Severe emotional instability is far more incapacitating than infrequent psychic equivalents, grand mal, petit mal and psychomotor attacks.

General physical and neurologic examinations have been repeatedly negative. Negative laboratory studies include x-ray examinations of the skull, psychometrics, urinalysis, complete blood count and blood sugar determination. The electroencephalogram disclosed a pattern consistent with convulsive disorder.

dl-Glutamic acid hydrochloride in conjunction with phenytoin therapy reduced petit mal seizures and psychic equivalents. A daily dose of 12 Gm maintained a urinary *pu* at about 5.0. Psychomotor and grand mal attacks were also reduced in frequency.

Improved mental and physical alertness was noted objectively and subjectively. Tolerance of the opinions of others was noticeably improved. Insight was acquired into her pronounced introversion, egocentric responses to minor stimuli, recurrent anxiety states and mild depressions. The efficiency with which she performed the details of her position as a librarian was augmented by the increased mental alertness. Gymnasium exercises became less laborious.

In this case petit mal attacks and psychic equivalents were decreased during the administration of *dl*-glutamic acid hydrochloride. A decided regression of mental and physical alertness followed withdrawal of the drug. Periodic rest in bed and a winter vacation were required to overcome a serious emotional instability.

CASE 8—J. K., aged 20, had had recurrent grand mal seizures for three years. General physical and neurologic examinations were negative. Negative laboratory examinations included a complete blood count, blood Kline test, urinalysis, x-ray examinations of the skull and psychometric studies. The electroencephalogram demonstrated a pattern commonly associated with convulsive disorder.

dl-Glutamic acid hydrochloride in 12 Gm daily doses reduced the urinary μ to about 50. Increased mental and physical alertness was noted, but only to a slight degree.

Seizures occurred at the pretreatment rate of one every one to two weeks. Phenytoin sodium in 0.4 Gm daily doses relieved the patient of seizures but had no effect on mental or physical alertness.

In this case, as noted previously, grand mal seizures were not affected by *dl*-glutamic acid hydrochloride.

COMMENT

Tolerance to *dl*-glutamic acid hydrochloride has proved surprisingly high. Gastrointestinal symptoms have been minimal. Objections to the taste have been alleviated by administration of the drug in capsules. Furunculosis has not occurred. Renal irritation has not been noted.

Improvement was noted in those cases in which the seizures are related to slow wave activity in the electroencephalogram, namely petit mal and psychomotor types. Seizures are decreased in frequency on medication which previously had been proved either ineffective or partially satisfactory. Petit mal seizures have been decreased from thirty to fifty to five to twenty-five daily in 1 case and from fifteen to twenty to three to five in another.

Universally, mental and physical alertness have been increased. The degree of improvement in mental efficiency cannot be correlated with the incidence of seizures. Without solicitation the patient, family and other interested parties have volunteered a favorable response to *dl*-glutamic acid therapy. Usually the patient is noted to be more energetic and happier, mood swings are less pronounced, behavior mannerisms are ameliorated and he is more congenial with associates.

Readministration of *dl*-glutamic acid hydrochloride was ineffective in 2 cases in both of which there was evidence of thyroid intoxication. Withdrawal of thyroid therapy was followed by a response similar to that of the initial treatment. In 2 other cases responses to readministration of the drug were quite similar to that of the initial treatment.

Ammonium chloride was administered in 2 cases (1 and 5). It proved ineffective in case 1, and severe acne resulted from its use in case 5.

Grand mal seizures were unaffected by the drug in 1 case (case 8). Focal motor cortical seizures and myoclonus likewise responded less favorably, as noted in cases 4 and 5 respectively.

It seems hardly necessary to emphasize that the beneficial effects of an additional aid in the treatment of epilepsy can be appraised only after a period of years. The preliminary results reported in this note may serve as a lead in further investigations. A comparison of the effect of *l*-glutamic and *d*-glutamic acid and their hydrochlorides as well as pyrrolidone carboxylic acid will show whether glutamic acid exerts a specific effect on the brain metabolism of epileptic patients.

SUMMARY

dl-Glutamic acid hydrochloride has been used in cases in conjunction with known anticonvulsant therapy. Seizures associated with slow wave activity in the electroencephalogram, namely petit mal and psychomotor types, were decreased in frequency. Increased mental and physical alertness have been most gratifying to patient, family and physician. Grand mal seizures were unaffected by the drug.

BULLIS FEVER

(LONE STAR FEVER—TICK FEVER)

AN ENDEMIC DISEASE OBSERVED AT BROOKE GENERAL HOSPITAL, FORT SAM HOUSTON, TEXAS

COLONEL JOHN C WOODLAND

MAJOR MORDECAI M McDOWELL

AND

CAPTAIN JOHN T RICHARDS

MEDICAL CORPS, ARMY OF THE UNITED STATES

During the spring and summer of 1942 many patients suffering from various acute febrile diseases were admitted to the contagious disease section of Brooke General Hospital, Fort Sam Houston, Texas. Most of these illnesses presented no great diagnostic problem, being recognized as seasonal diseases, such as infections of the upper respiratory tract, tonsillitis and mild influenza. In April it became apparent that in this group of patients we were confronted with a number of acutely ill ones who were suffering from a clinical disease entity which had defied definite identification. A search of the available literature failed to throw any light on this perplexing problem, and no report of similar cases could be found.

There were several outstanding clinical features characteristic of this disease, i. e. an unusually low white blood cell count with moderate neutropenia, a severe postorbital and occipital headache, and a constant lymphadenitis varying from involvement of a few glands to general lymphadenopathy. All the soldiers comprising this group were members of the field force of Fort Sam Houston, Texas, and all gave a history of having been on maneuvers at Camp Bullis, Texas, an area used for the training of troops of this post a week or more prior to the onset of symptoms. In all cases there was evidence of multiple tick bites, especially of the legs and thighs. In a great many instances, ticks were found still clinging to the skin of the patient at the time of admission to the hospital. In each instance the tick was identified as *Amblyomma americanum*, commonly known as the Lone Star tick, so named because of the star shaped marking on its back. While chigger bites were a common experience to all commands, massive exposure to tick bites was peculiar to men who had been on duty in the maneuver area at Camp Bullis, Texas.

Soon recognizing the fact that we were dealing with a disease entity which defied identification, the commanding officer of the hospital, Col George C Beach, M. C., in a communication to the Office of the Surgeon General, U. S. Army, in July 1942, requested the services of consultants especially qualified in this field of medicine. In response to this request Drs Kenneth F Maxcy, Norman H Topping and John C Snyder of the Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army arrived at the hospital on July 8, 1942. After a thorough examination of the patients suffering from this disease still remaining in the hospital and after minute scrutiny of the clinical records of those who had been returned to duty, these consultants agreed that we were dealing with a definite disease found only in those soldiers who had been subjected to tick bites at Camp Bullis. They

Dr Kenneth F Maxcy, consultant to the Secretary of War in the Board for the Investigation and Control of Epidemic Diseases in the Army, Dr Norman H Topping, passed assistant surgeon of the United States Public Health Service, and Dr John C Snyder staff member Rockefeller Foundation, International Health Division gave assistance and cooperation and constructive suggestions.

gave this syndrome a tentative designation of tick bite fever.¹ It was their opinion that the epidemiologic evidence associating this illness with tick bites was highly suggestive but that the causative agent had not been conclusively identified, nor could it be definitely shown at that time that the disease was transmitted to man through the medium of the tick bite.

SYMPTOMS

Usually the onset was abrupt with an initial chill or a chilly sensation ushering in the attack. Fever soon followed the temperature ranging from 102 to 105 F. A few of the patients gave a history of prodromal symptoms for a few days prior to the onset of chill and fever. A great majority of the men complained of post-orbital and occipital headache. Pronounced lassitude, prostration, anorexia and general weakness were noted during the febrile stage of the disease, and a few patients were nauseated and vomited. The fever lasted from four to fourteen days, with the temperature ranging from 102 to 105 F, and subsiding by lysis. In the average case the temperature was elevated for a little over five days. Convalescence was protracted, especially if the illness had been severe. Loss of weight was observed in a great many of the men, one patient losing more than 20 pounds (9 Kg.) within two weeks.

PHYSICAL FINDINGS

There was a paucity of physical findings in these patients, but all had an enlargement of at least one set of lymph glands and commonly general lymphadenopathy. The glands were easily palpable and in many instances were acutely tender. This glandular involvement persisted throughout the acute stage of the illness but disappeared rather promptly with the clearing of symptoms. The throat was usually slightly red and injected, but in none of the cases did the appearance resemble that usually seen in acute infection of the upper respiratory tract. In fact, complaints of involvement of the respiratory tract were conspicuous by their absence. Physical findings in the chest were normal, and roentgenograms failed to reveal any pathologic condition. In the more severe forms of the disease a maculopapular rash involving the trunk was noted. In some the eruption had the appearance of that seen in endemic typhus fever, and in others it resembled the rash seen in German measles. This manifestation of the syndrome rapidly faded and usually disappeared completely within forty-eight hours. In all instances examination revealed multiple tick bites.

LABORATORY FINDINGS

A constant laboratory finding characteristic of this disease was definite leukopenia occurring on or about the second or third day. In many instances the leukocyte count dropped to 3,000 and in one case to a low level of 1,750. With this abrupt drop in the total white blood cell count there was associated neutropenia, one patient having a polymorphonuclear count of 23 per cent. During the period of convalescence the total white blood cell count gradually approached normal, however moderate lymphocytosis persisted up to the time of discharge. The red blood cell count and the hemoglobin determination remained normal throughout the course of the disease. Urinalyses yielded negative results except in a few instances in which an occasional trace of albumin was noted. Specimens of blood from 6 patients

(cases 2, 3, 4, 30, 32 and 33 in the table) were examined at the National Institute of Health Laboratories for Q fever Rocky Mountain spotted fever and typhus by the complement fixation method. Completely negative results were obtained. Blood specimens were examined by the Weil-Felix test using *Proteus* X₁₉, X₂ and X₄, with negative results. Agglutination determinations were accomplished for undulant fever, tularemia, typhoid and paratyphoid A and B with negative results. Repeated blood cultures and smears were found negative. The heterophile antibody reaction was negative in all cases examined. Laboratory investigation of the spinal fluid in several cases yielded normal findings. Biopsy of enlarged lymph glands disclosed only lymphoid hyperplasia.

CLINICAL COURSE

There were no deaths in this series of cases, the disease being self limited. The syndrome varied from a mild febrile illness of short duration to a severe debilitating prolonged disease with a protracted convalescence. In the more severe forms a rash resembling German measles, and at times typhus made its appearance early in the disease but disappeared within forty-eight hours. In about 10 per cent of the cases skin manifestations developed. The elevation in temperature continued for about five days in a majority of the cases and returned to normal by lysis. The temperature once it reached normal remained normal except in a few instances in which an occasional rise to 99 F was noted. From clinical observation it is apparent that the incubation period of this disease is from seven to ten days.

TREATMENT

Patients were placed in bed during the acute stage of the illness and received routine nursing care. Codeine sulfate $\frac{1}{2}$ to 1 grain (0.032 to 0.06 Gm.) with acetylsalicylic acid 5 to 10 grains (0.32 to 0.65 Gm.) every two or three hours and an ice bag to the head were used for relief of the severe headache. The intake of fluids was encouraged. Dextrose and saline solution was given intravenously to patients showing dehydration from deficiency of fluid intake or from vomiting. Hydrotherapy was employed as indicated to combat the febrile reaction and to make the patient more comfortable. Chemotherapy was used in a few of the cases but was observed only to increase the toxicity associated with this disease. The syndrome was self limited and apparently it conferred immunity, since no recurrences have been observed. In this series of cases no complications or sequelae have been noted.

A TYPICAL CASE

Sergeant W. A. S. (case 1 in the table), infantryman, Fort Sam Houston Texas with two years' military service, was admitted to the Brooke General Hospital on June 25, 1942 complaining of severe generalized headache of four or five hours duration. His face was flushed as with fever and he appeared acutely ill. The onset of illness was sudden with nausea, vomiting and severe headache. He had noted no prodromal symptoms and no symptoms involving the respiratory tract. He gave no history of previous serious illness. Occupation habits and family history were noncontributory. He had been at Camp Bullis Texas, for one week, June 13 to June 20 inclusive and had returned to Fort Sam Houston five days prior to the onset of symptoms. While at Camp Bullis he suffered numerous tick and chigger bites. Physical examination revealed flushed skin and evidence of numerous insect bites on the abdomen and the legs. Moderate lymphadenopathy was found. Otherwise physical examination gave negative results.

¹ A Report of the Board for the Investigation and Control of Indian and Other Epidemic Diseases in the Army Aug. 10, 1942.

Laboratory Findings—Studies of the blood gave results as follows June 26 the white blood cell count was 4,600 with 84 per cent polymorphonuclears, 13 per cent lymphocytes and 3 per cent monocytes, the blood smear was negative for malarial plasmodia July 3 the white blood cell count was 3,550 with 41 per cent polymorphonuclears, 55 per cent lymphocytes and 4 per cent monocytes, the blood smear was negative for malarial plasmodia July 11 the white blood cell count was 6,800 with 43 per cent polymorphonuclears, 52 per cent lymphocytes and 5 per cent monocytes The red cell count and the hemoglobin content remained normal throughout

1 80 The heterophile antibody reaction was negative All the agglutinations were considered of no diagnostic significance
Progress in Hospital—June 27 the patient's temperature was still elevated There were no complaints other than headache—no nausea, no vomiting and no rash He was mentally clear Neurologic examination gave entirely negative results Some general weakness, lassitude and malaise were noted June 30 the patient still had generalized enlargement of lymph glands, and his temperature was still elevated He had no chills July 4, the fourth afebrile day, he was ambulatory and completely asymptomatic There was still generalized glandular

Complement fixation yielded negative results for Q fever Rocky Mountain spotted fever, and typhus Agglutination tests were negative, including Widal, Proteus X₁₀, X₂ and X_k, paratyphoid A and B undulant fever and heterophile antibody reaction

Urinalyses revealed only a slight trace of albumin during the febrile course of the disease
The spinal fluid cell count was normal The smear and the culture were negative The protein and globulin contents were normal, the gold curve was flat, the chloride and sugar levels were normal The spinal fluid pressure was normal The Wassermann reaction was negative
Tests for agglutination of Proteus X₁₀, X₂ and X_k were made on July 11, 14 and 17, with results as follows July 11, Proteus X₁₀ positive 1 160, X₂ negative, X_k negative, July 14, Proteus X₁₀ positive 1 80, X₂ negative, X_k negative, July 17, Proteus X₁₀ positive 1 80, X₂ positive 1 40, X_k positive

enlargement, which was the only constant physical derangement in this case July 8 the lymphadenopathy was no longer discernible There were no complaints July 17 convalescence was considered as uneventful The total white blood cell count was normal The patient still showed moderate lymphocytosis

A LABORATORY INVESTIGATION

The laboratory and field work to be reported now was accomplished by Col H R Livesay, Medical Corps, and Capt Morris Pollard, Veterinary Corps, of the Eighth Service Command Laboratory, Fort Sam Hou-

ton, Texas, in an attempt to determine the cause and the mode of transmission of this disease and to identify the vector.

Citrated and clotted bloods were inoculated intraperitoneally into rabbits and male guinea pigs. Spinal fluids with significant cytologic alteration were inoculated intracerebrally into guinea pigs, mice and rabbits. Spinal fluids and citrated bloods were also inoculated into developing 8 to 11 day old chick embryos by the chorioallantoic route and intravenous routes. In addition periodic serologic examinations were made for typhus, equine encephalomyelitis and lymphocytic choriomeningitis by the complement fixation test and for the Weil Felix reaction.

All serologic examinations yielded negative results. The spinal fluids in several cases induced a mild transient febrile reaction in guinea pigs by intracerebral inoculation on the ninth day after inoculation. One serial passage at this point of brain material to normal guinea pigs reproduced this reaction with no apparent increase in virulence of the agent. No histologic abnormality could be detected in the brain tissue. When the febrile reaction developed in guinea pigs, brain material was transferred to chick embryos. Five generations of chick embryos in series were killed after inoculation by the intra-

Temperature pulse and respiration

venous route within periods of six to nine days. There was no apparent increase in virulence of the agent by passage, and no lesions could be detected in the dead chick embryos. The spinal fluids induced no visible effect in mice or rats.

A consistent low grade febrile reaction was induced in guinea pigs with intraperitoneally inoculated citrated and clotted blood. This reaction developed on the ninth or tenth day after inoculation and usually lasted one or two days. No orchitis was observed in any of the guinea pigs inoculated, however fibrinous peritonitis developed in 2 instances, and this material is now being transferred to normal guinea pigs.

One hundred and fifty ticks collected at random from Camp Bullis were pooled, triturated in saline solution and inoculated into male guinea pigs. One guinea pig inoculated intracerebrally with tick emulsion showed a one day temperature of 106.2 F on the ninth day after inoculation.

Several deer armadillos and jack rabbits were examined from Camp Bullis, and no lesions were detected grossly or histologically. Of the ticks collected the predominating type was *Amblyomma americanum*, and several belonging to *Haemaphysalis leporis palustris* were removed from the jack rabbits.

No implication is being made as to the identity of the etiologic agent in these cases. The laboratory work is still in progress, and perhaps the results will merit a future report.

COMMENT AND CONCLUSION

The cases of 'Bullis fever' comprising this group resemble in some respects the cases of Colorado tick fever reported by Topping, Cullyford and Davis.² In those cases, however, a typical saddle back type of fever curve was noted, the initial fever lasting two or three days, then becoming normal only to rise again. In the cases under our observation this type of temperature curve was not seen, except that in a few cases a secondary rise to 99 F or slightly above was noted after a remission of one to three days. Lymphadenopathy, which was a constant finding in our series of cases, was not reported as found in the cases of Colorado tick fever. Dengue fever was thought of as a possible diagnosis, but the absence of exposure to mosquitoes and the clinical course of the disease aided in ruling out this condition as a possibility. Malaria was considered in view of the leukopenia, chills and fever, but this too was ruled out by the clinical course of the disease and by the negative blood smears. Acute mononucleosis was excluded by the negative heterophile antibody reaction, the absence of sore throat and the failure to find the typical white blood cells characteristic of this disease. Typhus and Rocky Mountain spotted fever were discarded as possibilities in view of the clinical course of the disease and the absence of laboratory findings in blood specimens. It is our opinion that Bullis fever constitutes a new disease entity heretofore undescribed.

All the men whose cases are included in this report gave a history of repeated and prolonged exposure to tick bites while undergoing training in the maneuver area known as Camp Bullis. This military reservation, approximately 20 miles west of Fort Sam Houston, Texas, has a heavy tick infestation.

Although no positive proof of the association of bites of *Amblyomma americanum* with this disease has been established, it is our opinion that further laboratory investigation will prove that this disease is transmitted to man through the tick bite. Recovery of the rickettsias of Rocky Mountain spotted fever from nymphs of *A. americanum* has been reported by R. R. Parker, G. M. Kohls and E. A. Steinhaus of the Rocky Mountain Laboratory of the National Institute of Health.³ With this proof at hand it is reasonable to suspect that the disease under discussion is transmitted to man by the same vector.

In view of the fact that there will be heavy troop concentrations in rural areas during the present national emergency, and since it is felt that this disease is more widely distributed than has been recognized, we feel that the attention of medical officers should be called to the occurrence of this syndrome. Unless the possibility of the presence of this disease is kept constantly in mind, it will challenge one's diagnostic acumen, since it resembles in many respects other acute febrile illnesses.

(It is apparent that this disease is increasing in frequency and severity in the San Antonio area. During the past two months [May and June 1943] 485 patients with the syndrome have been admitted to this hospital. A higher percentage of patients in this group have manifested the more serious symptoms and there has been

Bevan¹³ and Jensen and his co-workers¹⁴ also recently reported curves showing increasing solubility of these compounds with increasing p_H in water plus varying amounts of sodium hydroxide¹³ and in normal urine¹⁵

Chart 1—The solubility in nineteenth molar phosphate buffers of the urinary crystals from a patient receiving sulfadiazine. The values plotted represent the solubility of the acetyl-sulfadiazine component which was 93 per cent of the total crystal weight.

As shown in chart 1, sulfadiazine is approximately twenty times and acetyl-sulfadiazine thirty times, more soluble in buffers and in normal urine at p_H 7.5 than at p_H 5.0. In fact, at neutrality (p_H 7.0) sulfadiazine is approximately seven times and acetyl-sulfadiazine thirteen times more soluble than at p_H 5.0 (chart 2)

CLINICAL STUDIES OF THE PREVENTION OF CRYSTALLURIA AND RENAL REACTIONS DURING SULFADIAZINE THERAPY

From the facts that the precipitated products causing the renal toxicity from sulfadiazine in man are acetyl-sulfadiazine and, less frequently, free sulfadiazine (table 1) and that the solubilities of these compounds are much higher at p_H 7.0 and above than at p_H 5.0 to 6.0 (chart 2), it seemed likely that the maintenance of a neutral to slightly alkaline urine might prevent renal reactions during sulfadiazine therapy.

Studies of Patients Receiving the Usual Oral Dosages of Sulfadiazine—In a carefully controlled study of the incidence of crystalluria in acid and alkaline urines from 73 patients receiving 4 to 6 (usually 6) Gm daily of sulfadiazine and varying amounts of sodium bicarbonate, crystals were found in 27 per cent of 172 acid specimens and in only 1.4 per cent of 147 neutral or alkaline specimens¹⁶ (table 2).⁶ Factors other than p_H which might affect the incidence of crystalluria, namely the average daily urinary volume, the average specific gravity of the urine specimen examined and

the average daily dose of sulfadiazine, were essentially the same in the two groups. The urines examined were almost always the first specimens voided in the morning and were not refrigerated. These specimens were considered most appropriate for study since they are generally the most concentrated and most acid of the day. The daily urinary volume was usually between 1,200 and 2,500 cc, the specific gravity of the urine specimens examined was generally from 1.006 to 1.016. Twelve patients who had had crystalluria in acid specimens no longer had crystals after sufficient sodium bicarbonate was administered to render the urine neutral or alkaline. In 2 patients showing crystals in acid urines, crystals were still present on the first morning the urines were rendered alkaline by alkali therapy but were absent subsequently during the maintenance of alkaline urines. These two are the only instances in which crystals were observed in alkaline urine (table 2). It is suggested that these crystals were formed when the urine was acid and were being washed out of the urinary tract subsequently. On the other hand, we have observed gross crystalluria disappear in the first urine voided a few hours after the ingestion of 6 Gm of sodium bicarbonate. It is significant that crystalluria was observed frequently in acid urines of low specific gravity (1.006 to 1.010) as well as in acid urines of higher specific gravity.

Although renal complications result from precipitation of sulfadiazine compounds, it is not implied that the presence of rare or even gross crystalluria necessarily indicates the presence of renal complications. In fact, the incidence of crystalluria (approximately 30 per cent) in patients not treated with adjuvant alkali therapy is much higher than the incidence of discernible renal irritation or urinary tract obstruction (4.8 per cent⁵) in patients similarly treated.

In a series of 350 patients treated to date in the various services of the hospital with 6 Gm orally of

Chart 2—The curves of solubility of sulfadiazine and of acetyl-sulfadiazine in nineteenth molar phosphate and in tenth molar citrate p_H -5 sodium hydroxide buffer solutions of varying p_H values.

sulfadiazine per day and sufficient alkali to maintain the urine neutral or alkaline throughout the sulfadiazine therapy there have been no instances of crystalluria and no evidence of renal irritation or urinary tract

¹³ Roe F L, Martin A R and Bevan H G L. Sulfamethazine (2-Amino-6-methyl-4-methylamino-6,7-dimethylpyrimidine) a New Heterocyclic Derivative of Sulfanilamide. *J Pharmacol. & Exper Ther* 77: 177 (Feb) 1943.

¹⁶ The urinary p_H values in these studies were estimated with nitrazine 1-per and frequently checked by measurement with the Beckman glass electrode p_H meter. In particular instances when indicated the fresh urine specimens were immediately placed under toluene and the p_H determined shortly thereafter with the Beckman p_H meter.

obstruction attributable to the drug. The importance of these findings is obvious when compared with the incidence of approximately 30 per cent crystalluria (table 3) and 4.8 per cent of mild to more severe renal complications⁵ encountered in this hospital prior to the use of adjuvant alkali therapy.

Studies of Patients Receiving Large Oral Doses of Sulfadiazine—The effect of adjuvant alkali therapy has been studied in 9 patients¹⁷ receiving orally 12 to 15 Gm of sulfadiazine daily for periods of several weeks.

TABLE 2—Effect of Urinary pH on Incidence of Crystalluria from Sulfadiazine in 73 Patients Receiving 4 to 6 Gm of Sulfadiazine Orally per Day With or Without Varying Doses of Sodium Bicarbonate

	Acid Urines	Neutral or Alkaline Urines
Number of specimens	172	147*
Number of specimens with crystals	47	2
Percentage of specimens with crystals	27†	1.4

* 133 of these 147 urine specimens were from patients receiving alkali therapy.

† Some of these urines were from patients receiving small amounts of sodium bicarbonate, which accounts for the somewhat lower incidence of crystalluria in this analysis than in that of table 3 for patients receiving no alkali. The degree of crystalluria varied from rare crystals detected by microscopic study of several fields of the smeared, covered sediment to "gross" crystalluria.

to months. The blood sulfadiazine levels were from 12 to 25 mg per hundred cubic centimeters. The daily urinary volumes ranged from 1,000 to 3,000 cc. The total daily sulfadiazine excretion in the urine ranged from 9 to 14 Gm. Over 100 urine specimens from this group of patients were examined.

Although the incidence of renal complications in patients receiving such large dosages of sulfadiazine is very high when no adjuvant alkali therapy is given, none of these 9 patients showed crystalluria or any evidences of renal complications when the urines were maintained alkaline with 19.5 Gm of sodium bicarbonate daily in divided doses of 3.25 Gm (50 grains) every four hours. In 1 of these patients (L. C.) on two occasions during three months of therapy with 15 Gm of sulfadiazine and 19.5 Gm of sodium bicarbonate per day the alkali therapy was discontinued in order to ascertain with certainty its value. On both occasions crystalluria occurred when the urines became acid. On the first occasion there developed, shortly after the omission of alkali, pain in the loins with gross hematuria, which disappeared on resumption of alkali therapy, on the second occasion the alkali therapy was promptly resumed when acid urines with crystalluria and microscopic hematuria were voided. Similarly, in another of these patients (J. O.) receiving high dosages of sulfadiazine, gross crystalluria, microscopic hematuria and pain in the loins occurred on one occasion when the adjuvant alkali therapy was temporarily interrupted.

Studies of Patients Receiving 5 Gm Daily of Sodium Sulfadiazine Intravenously—In a study of 61 urine specimens from 23 patients receiving daily 5 Gm of sodium sulfadiazine intravenously in two doses of 2.5 Gm each and no adjuvant alkali therapy, most of the urines were found to be acid and the incidence of crystalluria was 43 per cent. These were surgical patients receiving intravenous sodium sulfadiazine therapy for approximately two to four days. All the urines containing crystals were acid. It is to be noted that the incidence of crystalluria in this group was appreciably higher than in patients receiving 6 Gm of sulfadiazine orally per day and no adjuvant alkali therapy (table 3). In 2 patients not included in the foregoing series, 1,000 cc of sixth molar sodium lactate solution per day was given intravenously in divided doses adjuvant to sodium sulfadiazine therapy. The urines of these patients were alkaline and there was no crystalluria.

The Appropriate Dosage of Adjuvant Alkali Therapy—The dosage of sodium bicarbonate necessary to maintain the urine neutral or slightly alkaline is variable, of course, in different patients. When alkalis are not administered, the urines of patients receiving sulfadiazine are almost always acid, usually from pH 5.0 to 6.0. This acidity is to be expected in part on the basis of the usual acidity of the urine in infection and in part because of the acidifying effect of the drug and its derivatives excreted in the urine. The acidifying effect of this sulfonamide is exemplified by our finding that the solution of 136 mg of sulfadiazine per hundred cubic centimeters decreased the pH of fifteenth molar phosphate buffer from 7.67 to 7.32. It is to be noted in this respect that the average concentrations in the urine of sulfadiazine and of acetylsulfadiazine are approximately 200 and 100 mg per hundred cubic centimeters respectively when the daily urine volume is 1,500 cc and the dosage of sulfadiazine 6 Gm per day.

The effects of 6 to 19.5 Gm of sodium bicarbonate daily on the urinary pH and incidence of crystalluria were studied in 40 patients and the findings compared with those in 23 patients receiving no adjuvant alkali therapy (table 3). An initial dose of 4 to 6 Gm of sodium bicarbonate was administered at the beginning of sulfadiazine therapy, and the daily doses were divided into six equal parts administered every four hours together with the sulfadiazine. Urine specimens known to contain urea splitting organisms were excluded from the analysis.

With doses of 6 to 12 Gm (average 8 Gm) daily of bicarbonate, the incidence of acid urines and of crystalluria was reduced only about one third (table 3).

TABLE 3—Study of Bicarbonate Dosage Required to Maintain Urine Neutral to Alkaline in Patients Receiving 4 to 6 Gm (Usually 6 Gm) of Sulfadiazine Orally per Day

Daily Dosage of Sodium Bicarbonate, Gm	Number of Patients	Number of Urines	Per Cent of Crystalluria*	Per Cent of Acid Urines
0	23	90	31	90
8†	13	71	18	59
13.7	10	39	0	15
19.5	17	51	0	0

* All the crystals were observed in acid urines.

† Average dosage in 13 patients receiving 6 to 12 Gm daily.

One patient in this group, who was receiving 12 Gm of alkali daily and who showed acid urines with crystalluria, developed gross hematuria. With 13.7 Gm of bicarbonate daily (six doses of 35 grains) the urines were usually neutral or alkaline, although 15 per cent were between pH 6.3 and 6.8. With 19.5 Gm daily (six doses of 50 grains) all the urines were alkaline. In both of these latter groups there was no crystalluria and no gross or microscopic hematuria. These doses of alkali were well tolerated, none of the patients had gastrointestinal symptoms and there were no clinical evidences of alkalosis. One patient who received 12 to 15 Gm of sulfadiazine daily for the treatment of sub-

17 Five of these patients were being treated for subacute bacterial endocarditis.

acute bacterial endocarditis also received 19.5 Gm of sodium bicarbonate daily for three months without showing intolerance to this medication.

COMMENT

Some other investigators have previously advocated adjuvant alkali therapy with sulfadiazine medication on the basis of their clinical findings.¹⁸ Schwartz and his collaborators¹⁹ reported a slight reduction in the incidence of crystalluria from oral sulfadiazine therapy in patients receiving sodium bicarbonate in amounts equal to the sulfadiazine.²⁰ The failure of the alkali therapy to produce a significant lowering of the incidence of crystalluria in this series¹⁹ can be attributed to the inadequate dosage of alkali as evidenced by our findings. Fox, Jensen and Mudge²¹ more recently have reported 2 cases of subacute bacterial endocarditis in which alkalis were used in conjunction with massive doses of intravenous sodium sulfadiazine. In these 2 cases complete anuria did not develop although renal reactions of less severity occurred; the authors²¹ point out that in these cases the amounts of alkali administered were insufficient to maintain the urines alkaline during the period of therapy and that precipitation occurred when the urines were acid. Schulte Shidler and Niebauer²² reported a case of acute urinary suppression following sulfadiazine therapy in which urinary flow was reestablished following oral alkali therapy and lavage of the kidney pelvis with 2 per cent sodium bicarbonate solution.

The present studies carried out on a large series of patients, showed that appropriate adjuvant alkali therapy prevented crystalluria, clinical evidences of renal damage and urinary tract obstruction from sulfadiazine therapy. This protection applied to patients receiving the usual therapeutic doses of sulfadiazine orally, large doses of sulfadiazine orally and the usual doses of sodium sulfadiazine intravenously. The clinical study of the effect of adjuvant alkali therapy was prompted by the chemical studies which demonstrated that the precipitate which caused the renal reactions was usually chiefly composed of acetylsulfadiazine²² (table 1) or, under particular circumstances, free sulfadiazine (table 1) and that the solubility of these pure compounds (chart 2) and of the urinary crystals (chart 1) was definitely greater at pH 7.0 and above than at the usual acidity of the urine of patients receiving sulfadiazine.

That fluids should be administered during sulfonamide therapy in quantities sufficient to maintain large daily urinary volumes is generally accepted and has

been widely advocated. It has further been shown repeatedly that severe renal reactions due to sulfonamide therapy are much more frequent in patients in whom the daily urinary volumes have been low during treatment with the drugs. The frequency with which mild or more severe renal reactions occur during treatment with sulfonamides in hospital patients on a regimen of carefully controlled therapy,² however, attests the fact that a feasible routine of fluid therapy is insufficient to prevent the occurrence of such reactions. That renal reactions occur during therapy with the usual daily doses of sulfadiazine or sodium sulfadiazine even when daily urinary volumes of approximately 1500 cc have been maintained, has been pointed out by Plummer and Wheeler.² In patients receiving larger doses of sulfadiazine without adjuvant alkali therapy the frequency of renal reactions is extremely high in spite of maximal fluid intake compatible with the comfort of the patient. It may also be pointed out that under certain circumstances, especially those incumbent on war operations today, sulfonamide therapy may be required under conditions in which amounts of fluid sufficient to afford more than a scanty urinary volume are not available. It is to be noted also that acidosis is often associated with dehydration. The remarkable effectiveness of an alkaline urine as a safeguard against renal reactions is a consequence of the fact that sulfadiazine is some twenty times, and acetylsulfadiazine some thirty times, more soluble at pH 7.5 than at pH 5.0 (chart 2).

From the results of studies with varying daily dosages of alkali it has been concluded that adjuvant therapy consisting of an initial 6 Gm dose of sodium bicarbonate followed by a daily amount of 15.6 Gm divided into 2.6 Gm (40 grain) doses administered every four hours is generally adequate to prevent crystalluria and renal reactions during oral therapy with 6 Gm of sulfadiazine. The dosage of alkali is increased or decreased in an individual patient when indicated by clinical or laboratory findings. The urinary pH may be tested simply with litmus or nitrazine paper, both of which indicators are blue in neutral and alkaline urines. The prescribed amount of 15.6 Gm of bicarbonate daily is conservative and is based on studies of patients in the Isolation Service of the New York Hospital (table 3). Twenty-four Gm of sodium bicarbonate daily has been administered routinely for short periods to obstetric patients receiving 6 Gm daily of sulfadiazine with no apparent ill effects²³ and no increase above normal in the carbon dioxide combining power of the plasma. It is necessary that the alkali be given in divided doses every four hours in order to maintain the urinary pH relatively constant throughout the day and night. Alkali therapy is continued for one day following cessation of sulfadiazine therapy. The same dosage of alkali should be used for patients receiving 4 Gm of sulfadiazine daily. Since micro-copic hematuria and pain in the loins sometimes occurs in ambulatory patients receiving 3 Gm of sulfadiazine daily, adjuvant alkali therapy should probably also be employed even with these small doses of sulfadiazine. We have employed the daily dosage of 19.5 Gm of bicarbonate in patients receiving 12 to 15 Gm of sulfadiazine by mouth daily. It should be noted that in patients with urinary tract infections with urea-splitting organisms the voided urine may be strongly alkaline as

22 That urinary crystals from sulfapyridine and sulfathiazole are chiefly the acetyl derivatives²³ of the drugs agrees with the observation that these derivatives are less soluble than are the free drugs (table 1). It has not been appreciated by many investigators, however, that the urinary precipitates from oral sulfadiazine therapy are generally composed chiefly of acetylsulfadiazine. This finding appears at first paradoxical since the true solubility of acetylsulfadiazine in buffers and in normal urine is greater than that of sulfadiazine (chart 1) and since the concentration of this derivative in the urine of patients receiving the drug is usually less than half that of the free drug (Plummer, Norman and Enright, *J. A. M. A.* 45:734 [Nov. 1940] and cannot be completely explained until further knowledge is available concerning the rate of solution of the urinary excretory products during sulfadiazine therapy. This problem is receiving study in this laboratory (Gilligan, Dorothy, Rourke and McDermott, Walsh. To be published). That free sulfadiazine would precipitate after intravenous injections of large amounts of sodium sulfadiazine intravenously is understandable.

23 Dr. R. Gordon Douglas, personal communication.

the result of ammonia production, nevertheless alkali therapy is still indicated in order to maintain the appropriate p_{H} in the urine in the tubules

Since intravenous therapy with sodium sulfadiazine in amounts of 5 Gm per day occasions a particularly high incidence of crystalluria and of renal complications,⁵ adjuvant alkali therapy is obviously indicated with such a regimen even though it should be necessary to administer the alkali by the intravenous route. The sodium sulfadiazine itself provides an insignificant amount of alkali, since 5 Gm of this drug has the sodium content (0.42 Gm) of only 1.5 Gm of sodium bicarbonate.

Loughlin and his collaborators²⁴ have recently shown that the blood level of sulfadiazine rises approximately twice as fast when 4 Gm of sodium bicarbonate is given orally together with a single 4 Gm dose of sulfadiazine as when the sulfadiazine is given alone. This advantage of increasing the blood level more rapidly would be especially when the initial dose of 6 Gm of bicarbonate is given, as prescribed at the onset of therapy.

with sulfadiazine. The data of these authors²¹ show a considerably higher percentage of acetylation of the sulfadiazine in the blood when bicarbonate was given with a single dose of sulfadiazine than when sulfadiazine was given alone. Daily blood and urine studies made by us on a group of patients receiving daily adjuvant alkali therapy showed no higher percentage of acetylation of the sulfadiazine than when sulfadiazine was given alone.

Alkalosis should not be encountered during the regimen of adjuvant alkali therapy that has been outlined, since it has been shown that only sufficient alkali need be administered to maintain the urine neutral to slightly alkaline, whereas the normal kidney has the capacity of excreting alkali sufficient to produce a urinary p_{H} of 8.2.²⁵ Bischoff²⁶ has demonstrated that

24 Loughlin E. H., Bennet, R. H., Flanagan, Mary E., and Spitz, S. H. Relative Absorption and Conjugation of Nine Compounds by Humans During a Three Hour Period (Free and Conjugated Blood Level Determinations During a Three Hour Period Following Peroral Administration of the Acid Salts Alone, the Acid Salts with Sodium Bicarbonate and the Sodium Salts of Sulfapyridine, Sulfathiazole and Sulfadiazine), *Am. 30 Gm of sodium citrate daily is the minimum dosage of alkali which produces a shift in the acid base equilibrium of the plasma outside the normal variation of the normal individual. In a series of patients studied here who received as much as 24 Gm of sodium bicarbonate together with 6 Gm of sulfadiazine daily, the plasma bicarbonate values were all within the limits of normal.

In some instances, such as in cardiac or renal insufficiency, adjuvant sodium bicarbonate therapy may be contraindicated. However, the incidence of severe renal reactions in such conditions during sulfadiazine treatment without appropriate fluid and alkali therapy is very high.²⁷ It would seem that the seriousness of a possible severe renal reaction from sulfadiazine would outweigh the danger of increasing edema by adjuvant therapy with fluid and alkali in a patient with cardiac decompensation during a short period of treatment for an acute infection. It may be that a potassium salt of an organic acid can be used in place of a sodium salt in cardiac patients, however, increased potassium in the blood has been shown experimentally to produce cardiac arrhythmias.²⁸ The same caution must be exercised in the administration of alkalis as in the administration of the sulfonamides for patients with renal insufficiency.

Sodium lactate or sodium citrate may be preferred to sodium bicarbonate for adjuvant alkali therapy. These former salts do not act as alkalis in the alimentary tract and therefore should be substituted for sodium bicarbonate for any patient in whom the latter salt causes gaseous eructations, nausea or a purgative effect. The dosage of sodium lactate is one third greater and that of sodium citrate ($\text{Na}_3\text{C}_6\text{H}_5\text{O}_7 \cdot 2\text{H}_2\text{O}$) approximately one fifth greater than that of sodium bicarbonate, i. e., 20.8 Gm of sodium lactate or 18.2 Gm of sodium citrate afford an equivalent alkali excess to that of 15.6 Gm of sodium bicarbonate. Sterile, isotonic (sixth molar) sodium lactate solution affords a means of giving alkalis intravenously. One hundred cc of this solution (sixth molar) is equivalent to 1.4 Gm of sodium bicarbonate.

That crystalluria is rarely²⁹ encountered during therapy with sulfanilamide is attributable to the greater solubilities of this drug and its acetyl derivative compared with sulfapyridine, sulfathiazole and sulfadiazine and their acetyl derivatives. Investigation of the value of adjuvant alkali therapy in preventing renal complications from sulfadiazine would perhaps have been made much earlier if it had not been common clinical experience that alkali therapy was of no value in preventing renal complications from sulfapyridine. The explanation for this failure is now known to reside in the solubility characteristics of sulfapyridine and its acetyl derivative, there is no increase in their solubility with increasing p_{H} within the physiologic range of urinary p_{H} (table 4), whereas sulfadiazine and acetylsulfadiazine are much more soluble in the alkaline than in the acid range of urinary p_{H} . Schwartz and his collaborators¹⁹ have reported a significantly lower incidence of crystalluria from sulfathiazole when sodium bicarbonate was administered in equal doses to those of the drug than when sulfathiazole was given without alkali. Further clinical studies on the prevention of renal complications from sulfathiazole with larger doses of alkali

have not to our knowledge been published. The solubility in buffers of acetylsulfadiazine of which the urinary crystals are composed,¹⁰ increases only from 7 mg per hundred cubic centimeters at pH 5.5 to 28 mg per hundred cubic centimeters at pH 7.5 whereas the solubility of acetylsulfadiazine increases from 20 mg per hundred cubic centimeters at pH 5.5 to 512 mg per hundred cubic centimeters at pH 7.5. Two substituted sulfadiazine compounds sulfamerazine and sulfamethazine are at present receiving clinical study in this country and abroad.¹¹ These clinical studies have been prompted largely by the greater solubilities of these substituted sulfadiazine compounds and of their acetyl derivatives than of sulfadiazine and acetylsulfadiazine in the acid range of urinary pH (table 4).

CONCLUSIONS

1 The urinary precipitate which causes renal complications and obstruction to urinary flow during oral sulfadiazine therapy usually consists chiefly of acetylsulfadiazine. Free sulfadiazine sometimes precipitates in the urine after intravenous sodium sulfadiazine.

2 The urine is almost always acid (usually pH 5.0 to 6.0) in patients receiving sulfadiazine without adjuvant alkali therapy. With minor exceptions crystalluria from sulfadiazine is found only in acid urines.

3 The solubilities of sulfadiazine and of acetylsulfadiazine in buffers and in urine increase a great deal with increasing pH within the physiologic range of urinary pH . The amounts of sulfadiazine and of acetylsulfadiazine dissolved in a given volume of buffer solution or normal urine at pH 7.5 are approximately twenty and thirty times respectively the amounts dissolved at pH 5.0.

4 Crystalluria and evidences of renal damage or of urinary tract obstruction were not encountered in 350 patients in whom the urine was maintained neutral or alkaline by adjuvant alkali therapy during treatment with 6 Gm daily of sulfadiazine or in smaller groups of patients receiving twice this dosage of sulfadiazine orally or sodium sulfadiazine intravenously.

5 On the basis of clinical studies 15.6 Gm daily of sodium bicarbonate (or amounts of other organic sodium salts with equivalent available base excess), divided into six doses of 2.6 Gm (40 grains) administered every four hours is recommended as the dosage usually appropriate to maintain the urine neutral or slightly alkaline during sulfadiazine therapy in adults. Regimens of alkali therapy for patients receiving unusually large doses of sulfadiazine orally or sodium sulfadiazine intravenously have also been adopted. A sufficient volume of fluid should be given to provide a daily urinary output of 1500 cc or more.

6 The findings of these laboratory and clinical studies lead to the conclusion that renal damage and urinary tract obstruction consequent to precipitation of sulfadiazine and acetylsulfadiazine are preventable and that adjuvant alkali therapy sufficient to maintain the urine neutral or slightly alkaline should be prescribed whenever sulfadiazine is administered.

THE PRODUCTION OF DIABETES MELLITUS IN RABBITS WITH ALLOXAN

A PRELIMINARY REPORT

C CABELL BAILEY, MD

AND

ORVILLE T BAILEY, MD

BOSTON

In 1937 Jacobs¹ found that alloxan² (the ureide of mesoxalic acid) produced fatal hypoglycemia when injected intravenously into rabbits. No histologic observations were recorded. Similar experiments conducted by Dunn, Sheehan and McLetchie³ confirmed the hypoglycemic action of alloxan. On microscopic study these observers found necrosis of all the islets of Langerhans while the acinar tissue escaped injury. All but 1 of their animals died apparently in hypoglycemia.

It alloxan produces extensive necrosis of the islets of Langerhans without apparent damage to the acinar tissue and relatively minor changes in other organs, it seemed to us that the hypoglycemic phase might be transitory. Should this be true, animals kept alive by repeated injections of dextrose might survive this phase and finally develop diabetes mellitus. A series of experiments designed to test this hypothesis has shown that such is the case. Six 3 months old male Dutch rabbits were used. Each received intravenously 200 mg of alloxan per kilogram of body weight. The injection was made in three equal parts over a period of forty-five minutes. Blood sugars were determined every fifteen minutes for the first two or three hours and at hourly intervals thereafter. The rabbits were observed constantly for sixteen to twenty-four hours, and 50 per cent dextrose was given intravenously whenever hypoglycemic convulsions occurred. Frequent rectal temperatures were recorded and the clinical condition of the rabbits was constantly watched.

After the first twenty-four hours some of the animals were placed in metabolism cages where water intake and urine output and urinary sugar could be accurately followed. All of the animals have been under close observation and frequent blood sugars and nonprotein nitrogens⁴ have been determined.

Our results fully confirm the findings of Jacobs¹ and of Dunn, Sheehan and McLetchie³ in regard to the initial transitory hyperglycemia lasting approximately one hour immediately after injection of the material and followed by severe hypoglycemia with convulsions. In less than twenty-four hours the hypoglycemic stage had ended leaving the animals with severe diabetes mellitus which has persisted in 5 of the 6 animals during a period of two weeks observation. During this period blood sugar levels have ranged from 360 to 700 mg per

Mrs. Rachel Smith Leach supervised the chemical analyses and gave valuable technical help. Miss Virginia Kent assisted in the chemical determination.

hundred cubic centimeters, glycosuria has been found up to 10 per cent. Rabbit 3, not given insulin, developed acetonuria and pronounced lipemia (total blood lipids 8,412 mg per hundred cubic centimeters). The blood acetone⁵ (total acetone bodies expressed as acetone) reached 144 mg per hundred cubic centimeters of blood at the time the animal was killed with air embolism. Rabbit 5 had a blood sugar of 360 mg per hundred cubic centimeters of blood twenty-four hours after injection. At the end of forty-eight hours the blood sugar returned to normal and has remained so for a period of one week's observation. Rabbits 1 and 6 have received 1 to 4 units of insulin daily to control their diabetes, which has persisted for the total period of observation. Rabbit 2 had been receiving 2 units of insulin daily when it developed severe diarrhea and died on the fourteenth day after injection. Apparently this death was not related to alloxan.

Rabbits 3 and 4 have thus far been killed. In each animal all the cells (both alpha and beta) of all the islets of Langerhans had disappeared completely. No polymorphonuclear leukocytic infiltration was seen. The blood vessels of the islets were preserved and appeared entirely normal. Some of the pancreatic ducts were moderately distended and contained eosinophilic material. Their epithelium, as well as all the acini, showed no changes detectable on microscopic examination. Studies on organs other than the pancreas have not yet been completed.

The following is a representative experiment in the series.

Rabbit 1, weighing 1,520 Gm, was entirely normal during a seven day period of observation. Food was withheld for eighteen hours, at the end of which time two micro blood sugar determinations⁷ were 105 and 100 mg per hundred cubic centimeters. Three hundred and four mg of alloxan (200 mg per kilogram of body weight) was then injected intravenously in three divided doses at fifteen minute intervals. Fifteen minutes after the end of the last injection the blood sugar was 208 mg per hundred cubic centimeters. An hour later it was 105 mg per hundred cubic centimeters and two and one-half hours after the end of the injection it was 38 mg per hundred cubic centimeters. The first convulsion developed ten minutes later. Prompt recovery followed the administration of 2 cc of 50 per cent dextrose intravenously. In the next thirteen hours eleven more hypoglycemic convulsions occurred, each relieved promptly by dextrose intravenously. On the morning after the injection of alloxan the blood sugar was 190 mg per hundred cubic centimeters and rose to 640 mg per hundred cubic centimeters on the third day. The rabbit has been kept in good condition for sixteen days by the administration of 2 to 4 units of insulin daily. The amount of insulin required has constantly increased and the blood sugars have varied from 200 to 540 mg per hundred cubic centimeters. Persistent glycosuria has accompanied the hyperglycemia, the daily dextrose excretion varying between 10 and 22 Gm.⁸ Definite polydipsia and polyuria have been observed with water intake ranging between 350 and 700 cc and urinary excretion between 160 and 470 cc daily. The body temperature was 104 F before the experiment was begun and fell to 99 F at the end of eleven hours but subsequently returned to normal.

Repeated urinalyses have failed to show albuminuria or any abnormal sediments. Blood nonprotein nitrogens⁴ have varied

from 36.3 to 65.0 mg per hundred cubic centimeters, whereas normal controls taken prior to the experiments ranged from 42.6 to 60.0 mg per hundred cubic centimeters.

COMMENT

From these experiments it seems clear that the intravenous administration of alloxan in rabbits in doses of 200 mg per kilogram of body weight produces an immediate transitory rise in blood sugar followed by hypoglycemia of several hours' duration. If hypoglycemic death is prevented by repeated administration of dextrose an apparently permanent state of hyperglycemia develops within twenty-four hours. Our histologic observations confirm the work of Dunn, Sheehan and McLetchie⁹ that selective injury to the islets of Langerhans is produced by alloxan. This is probably the basis for the permanent hyperglycemia. In view of previous work done in this laboratory⁹ as well as in other laboratories¹⁰ the initial blood sugar rise, which lasts about one hour, may be similar to a transitory hyperglycemia easily produced in rabbits by the injection of a number of substances. The cause of the prolonged yet limited period (twelve to twenty-four hours) of hypoglycemia which follows is at the present time debatable. Dunn, Sheehan and McLetchie⁹ suggest that it may result from a primary stimulation of the islet cells. Another possible explanation may be that necrosis of the islets releases a large amount of insulin. In either case the destruction of the pancreatic islets probably explains the subsequent, apparently permanent, diabetes.

Whatever the mechanism involved, the use of alloxan provides a simple method for the production of diabetes mellitus in rabbits in the laboratory within twenty-four hours. The diabetes mellitus thus induced bears many resemblances to the human disease. There is definite and persistent hyperglycemia and glycosuria with polydipsia and polyuria, the response to insulin is prompt, when insulin is withheld acetonuria and hyperlipemia may develop. These animals offer acceptable subjects for investigation of many problems of diabetes mellitus as well as in carbohydrate metabolism.

This is a preliminary report, and further studies are being undertaken in regard to the effects of alloxan on various organs as well as the consequences of different dosages of this drug.

SUMMARY

Alloxan when given intravenously to rabbits produces necrosis of the islets of Langerhans. Brief hypoglycemia, if counteracted by repeated injections of dextrose, is followed by the development of symptoms seen in human diabetes, namely hyperglycemia, glycosuria, polydipsia, polyuria, acetonuria and lipemia.

Origin and Nature of Allergy—The view is now generally accepted that the mechanism of allergic phenomena is based on an antigen-antibody reaction taking place in the cells or tissues. This reaction has also been called the allergen reaction. Furthermore, it has now been definitely established that neither the antigen (allergen) nor the antibody is in itself the noxious agent and that rather the union of the two initiates the clinical response. The proof of this consists of experiments that have shown that when an organism's supply of antibodies has been depleted renewed exposure to the antigen does not elicit any pathologic changes.—Urbach I. Rich and Gottlieb Philip M. Allergy, New York, Grune & Stratton 1943.

XANTHOMATOSIS

A CAUSE OF CORONARY ARTERY DISEASE
IN YOUNG ADULTS

LIEUTENANT HYMAN ENGLBLERG

AND

MAJOR BEN A. NEWMAN

MEDICAL CORPS, ARMY OF THE UNITED STATES

Though xanthomatosis is but a single manifestation of a systemic pathologic condition only recently has this disturbance in cholesterol metabolism seriously occupied the attention of any one but the dermatologists. Lately the occurrence of cardiovascular involvement with cutaneous xanthomatosis has likewise been noted by the internists¹ but because of the meagerness of the literature on the subject the impression is prevalent that this association is rare. To emphasize the fact that this is not an infrequent occurrence we are presenting 6 cases of xanthomatosis and coronary artery disease that we have seen during the past two years, illustrating their diagnostic features.

REPORT OF CASES

CASE 1—L. W., a man aged 32, first seen in June 1941, complained of substernal pain on exertion and after heavy meals. The family history revealed that his father had died of a heart attack at 48 and his mother of heart disease at 62. Physical examination was negative except for a small pinhead size, yellowish papule on the left lower eyelid. The blood pressure was 120/70. The basal metabolic rate was 16 per cent. The Wassermann reaction was negative. An electrocardiogram (fig 1) was normal at rest but after exercise showed a temporary depression of the ST segment in leads 1, 2 and 4 F. With exercise a typical attack of his substernal pain developed. It was felt that he had coronary insufficiency and moderation of activity was advised. Four weeks later the patient mentioned that the yellow papule of the eyelid had increased to double its size. He also stated that his younger sister had similar lesions on both eyelids. The blood cholesterol at this time (July 21) was 430 mg per hundred cubic centimeters and the esters 238 mg per hundred cubic centimeters. The fasting blood sugar was within normal range. He was placed on a diet low in animal cholesterol. On September 11 the blood cholesterol was 373 mg per hundred cubic centimeters and the esters 273 mg per hundred cubic centimeters. During this interval he had symptomatically improved. In December after unusually severe exertion, he experienced sharp pain in the chest which persisted for several hours. After this the sedimentation rate became rapid and the abnormal electrocardiographic changes that had been observed only after exercise were now present at rest (fig 1C). A diagnosis of acute myocardial infarction was made. The patient was kept at bed rest for four weeks and then gradually resumed limited activity. He is now asymptomatic even with moderate exertion. The blood cholesterol in December was 290 mg and the esters 170 mg. Since the beginning of the diet low in animal cholesterol the xanthoma of the eyelid has not increased in size.

Significant Features—Familial tendency shown by early cardiac death of the father and xanthomas of the sister's eyelids; normal blood pressure, xanthoma of the skin; onset of angina pectoris at the age of 32, hypercholesteremia with moderate reduction with diet; simultaneous onset of cardiac symptoms and cutaneous lesions.

CASE 2—N. G., a man aged 48,² had an attack of acute coronary thrombosis at the age of 40. In the following five years there were many episodes of severe precordial pain, always mitigated by exertion. Examination revealed large masses at each elbow and nodules along the tendons of the hands and feet. According to the patient's story these masses and small nodules along the tendons of the hands and feet had appeared soon after his first cardiac pain. Biopsy of the nodule at the elbow revealed typical xanthomatosis. His blood pressure was 140/90 and the patient definitely stated that on many previous examinations hypertension had never been found. The fasting blood sugar was normal, the blood cholesterol was 275 mg and the esters 190 mg per hundred cubic centimeters. Electrocardiograms over several years showed progressive changes with an advanced degree of myocardial damage (fig 2). One year before admission six years after the onset of heart disease, he suffered a cerebral accident with paraplegia. Recovery from this has been almost complete. A low cholesterol diet has been maintained for years without decrease in the blood cholesterol and esters.

Significant Features—Acute coronary thrombosis at 40 years, normal blood pressure, hypercholesteremia with no response on low cholesterol diet; tendon sheath xanthomas, which appeared shortly after the first symptoms of cardiac involvement.

CASE 3—L. A. W., a man aged 33 first seen in January 1941 complained of episodes of precordial pain on exertion occurring with increasing frequency. His father had died at the age of 40 of acute coronary thrombosis. Examination was

FIG. 1 (case 1)—Tracings made (A) at rest (B) immediately after exercise with pain present and (C) six days after severe precordial pain at several hours duration in December 1941.

completely negative. The blood pressure was 120/80, the urine was normal. One week after the onset of the first anginal episode he suffered a typical attack of acute coronary thrombosis (fig 3). Recovery was complete and he has been well ever since. In May 1941 as this paper was being written it was felt that in view of the family story of heart disease at an early age xanthomatosis might have been the basic condition despite the absence of cutaneous lesions. A blood cholesterol determination done at this time was 305 mg per hundred cubic centimeters of plasma. The basal metabolic rate was -7 per cent. Fasting blood sugar 93 mg.

Significant Features—Familial history of coronary thrombosis early in life; normal blood pressure; acute coronary thrombosis at the age of 33; hypercholesteremia with absence of cutaneous manifestations of xanthomatosis.

CASE 4—I. M., a woman aged 48 complained chiefly of attacks of precordial pain on exertion during the past year. Her father had died of heart disease and her mother died

Dr. M. H. Nathanson gave the authors the privilege of following 2 of the cases presented.

From the Departments of Internal Medicine and Dermatology, Cedars of Lebanon Hospital, Los Angeles.

1. Thannhauser S. J. and Magendanz Heinz. Ann. Int. Med. 11, 162-176 (March) 1938. Müller Carl. Angina Pectoris in Hereditary Xanthomatosis. Arch. Int. Med. 64: 675 (Oct) 1939.

2. Newman B. A. Xanthomatosis with Disease of the Coronary Arteries. Arch. Derm. & Syph. 15: 193-199 (Jan.) 1941.

suddenly while doing housework. The patient volunteered the information that she had noticed the appearance of yellow plaques on both eyelids about the time that she had her first attack of pain. Examination was negative except for xanthomatous plaques on the inner portion of all eyelids. Blood pressure varied from 150/80 to 170/90. Fluoroscopy of the

Fig. 2 (case 2)—Tracings showing changes indicative of advanced degree of myocardial damage.

heart in both oblique views revealed no chamber enlargement, which was evidence against any previous, persistent hypertension. The urine was normal, the fasting blood sugar was 129 mg per hundred cubic centimeters, the blood cholesterol was 333 mg per hundred cubic centimeters of plasma. The electrocardiogram did not reveal any abnormality. The patient gradually improved on a regimen consisting essentially of modified activity, a low cholesterol diet and xanthine vasodilating drugs.

Significant Features—Familial history of heart disease, coronary insufficiency in the absence of diabetes or persistent hypertension, hypercholesteremia, onset of cardiac symptoms and xanthoma of the skin at approximately the same time.

CASE 5—N. B. O., a married woman, aged 45, first entered the clinic in March 1941 complaining chiefly of pains in the knees and mild precordial pain following exertion. She stated that, twenty years before, nodules appeared on both achilles tendons and yellow plaques were noticed on both eyelids. Five

Fig. 3 (case 3)—Tracings made one week after attack of severe chest pain, revealing infarction of the anterior wall.

years after their appearance the tendon nodules were excised because their large size had caused discomfort. They promptly recurred. The family history revealed that two brothers had similar skin lesions and one brother had sustained an acute coronary thrombosis in his early forties. Examination revealed large, subcutaneous masses the size of a fist on each achilles tendon, with smaller nodules along the tendons of the dorsum

of the hands and feet. There were yellow nodules at the knees and elbows and yellowish plaques on the upper and lower eyelids. Blood pressure was 130/80, the basal metabolic rate was -15 per cent. The blood cholesterol was 465 mg per hundred cubic centimeters. The fasting blood sugar level was normal. An electrocardiogram was normal (fig. 4A). Immediately after exercise, however, there was epigastric distress and a depression of the ST segment in leads 1 and 2 and inversion of the T wave in lead 4F (fig. 4B). After one hour of rest the electrocardiogram was again normal (fig. 4C).

A diet free of animal fat was prescribed but follow-up was incomplete, as she did not return to the clinic and could not be traced.

Significant Features—Familial history of xanthomatosis and early heart disease, a twenty year interval between the appearance of the skin and tendon lesions and the heart symptoms, normal blood pressure, hypercholesteremia.

CASE 6—C. N., a married woman aged 31 entered the clinic in 1939 because she had noticed swellings on the achilles tendons. The family history was not significant. Examination was negative except for the hard, nodular swellings on both achilles tendons. The blood pressure was 116/74. Biopsy of the nodules revealed typical evidence of xanthomatosis. The blood cholesterol at this time (August 1939) was 333 mg per hundred cubic centimeters, the basal metabolic rate was -21 per cent, the urine was normal. The patient was put on a low cholesterol diet, and desiccated thyroid was prescribed but was not well tolerated. In January 1940, one year after

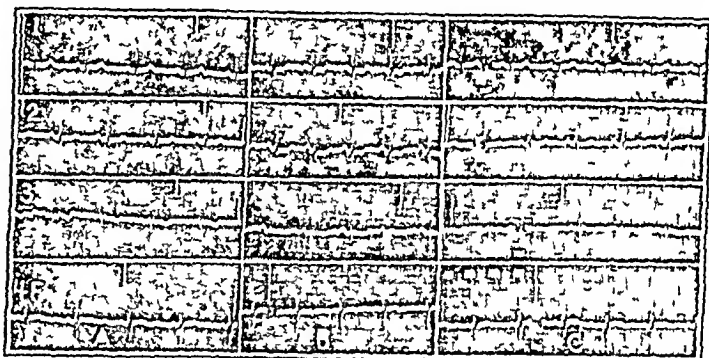

Fig. 4 (case 5)—Tracings made (A) at rest (B) with exercise showing depressed ST segment in leads 1 and 2 and inverted T₁ (C) after one hour of rest, electrocardiogram is again normal.

the appearance of the tendon lesions, she began to complain of precordial palpitation. Clinically, extrasystoles were noted. In June 1940 she began having precordial pain. An electrocardiogram at this time was not considered definitely significant but an electrocardiogram taken eight months later showed a flattening of T₁ and T₂ and an inversion of T₁ (fig. 5). During this time, despite the low cholesterol diet which she followed, repeated determinations showed a blood cholesterol of between 430 and 450 mg per hundred cubic centimeters and cholesterol esters ranging between 290 and 320 mg per hundred cubic centimeters.

Significant Features—Xanthomatous nodules of tendons, hypercholesteremia, heart symptoms and electrocardiographic changes at the age of 32 in the absence of diabetes or hypertension, no response on low cholesterol diet.

COMMENT

The cases presented are quite typical of the syndrome of xanthomatosis associated with coronary disease and serve to illustrate the significant features of this condition.

1 Familial Tendency—This was present in 4 of our 6 cases. The available evidence in the literature in which xanthomatous families have been traced through four generations reveals that it is a dominant hereditary disease. Muller¹ presented 68 cases occurring in seven families. Recently a family was described in

which 4 children between the ages of 6 and 23 years died of xanthomatosis of the cardiovascular system. The authors³ discussed thoroughly the genetic aspects of the disease and stated that although it might be a dominant factor it could be explained also as simple recessiveness.

2 *Age at Onset of Heart Disease*—In 2 of our cases (1 and 3) acute coronary thrombosis occurred at the age of 32 and 33 respectively. In 5 the initial evidence of cardiac involvement was relatively early in life. Apparently this is a disease which may affect the cardiovascular system of all age groups. In the literature involvement of the coronary artery in the first decade of life has been reported. On the other hand the first manifestations may not occur until middle age or later in life.

3 *Sex*—Our patients were equally distributed between the two sexes in contradistinction to the usual predominance of coronary disease in males.

4 *Type of Cardiovascular Involvement*—Coronary insufficiency was present in all cases. In 1 the cerebral vessels were also sclerotic. Though coronary disease is the most frequent type of vascular involvement the heart valves are occasionally affected and cases have been reported in which the aorta and pulmonary arteries

Xanthoma tuberosum the most common variety, is characterized by lesions occurring predominantly on the extensor surfaces of the extremities. They may be single or multiple, small or large firm nodules more often on the elbows, knees or knuckles. The cutaneous

Fig. 6—Xanthoma of eyelid showing minimal lesion.

nodules are yellow or chamois colored and the tendon or tendon sheath xanthomas are subcutaneous without alteration in the color of the overlying skin. In this type there is generally a definite elevation of the blood cholesterol level and an increase in the content of total blood lipids.

Fig. 7 (ca e 2)—Xanthoma of achilles tendon.

Xanthoma palpebrarum, often classified as a separate variety, may belong in the tuberosus group and is frequently found associated with other nodules or may precede their appearance. Even when present alone, there is frequently a moderate hyperlipemia and cardiovascular xanthomatosis.

Fig. 5 (ca e 6)—A, June 1940. B, eight months later. T₁ and T are now flat. T₁ is inverted.

were greatly narrowed. Peripheral vessels are often sclerotic, and claudication may be the chief or primary symptom.

We have seen 2 cases of tendon sheath xanthomatosis in young adults with hypertension and coronary disease. We have not included them in this series because the coronary sclerosis may be secondary to the hypertension rather than xanthomatous in origin. It is our opinion that in these cases the hypertension is secondary to sclerosis of the renal vessels an aftermath of the disordered cholesterol metabolism. This interpretation is supported by the fact that the tendon sheath lesion had been present for several years prior to the onset of the hypertension.

5 *Types of Xanthomatosis of the Skin Associated with Cardiovascular Disease*—Basically two types of cutaneous xanthomatosis exist—xanthoma tuberosum and xanthoma disseminatum. The latter, a more rare disturbance, is characterized by multiple small yellowish papules scattered over the flexural surfaces of the body and the mucous membranes. In this type the blood lipids are within normal limits and diabetes insipidus is not infrequent. This disseminated variety is rarely associated with cardiovascular disease.

6 *Variations in Blood Cholesterol*—Hypercholesteremia of varying degree was present in all 6 cases. The blood cholesterol is usually elevated in this syndrome, but not necessarily so. The three cardinal signs—hypercholesteremia, skin or tendon xanthoma and coronary insufficiency—frequently occur together, but any one or two of the triad may be absent or precede the other. In 2 of our patients the skin and heart involvement occurred simultaneously, and in 1 there was no skin or tendon sheath xanthomatosis.

7 *Diagnosis in the Absence of Skin Lesions*—When skin or tendon sheath xanthomas are present, attention is immediately directed to the correct diagnosis. However, there are certain features that should lead one to suspect the presence of xanthomatous coronary disease in the absence of the superficial lesions. Coronary insufficiency in women in the absence of diabetes or hypertension calls for a determination of the blood cholesterol. Likewise when coronary insufficiency is present in young adults particularly when there is a family history of early cardiac death or coronary disease, this syndrome should be considered.

8 *Cause*—Although our period of observation has been limited, there does not appear to be any difference between the course of xanthomatous coronary sclerosis and arteriosclerotic coronary disease. Acute coronary thrombosis may occur at any time. However, the possibility of modifying or arresting the progress of this type of coronary disease by therapy is more hopeful than in arteriosclerosis.

9 *Therapy and Prophylaxis*—Therapy is meager. A low cholesterol diet may reduce the hypercholesteremia. This occurred in only 1 of our 3 patients who followed the diet faithfully. Thannhauser¹ has shown that on such a diet the xanthomatous patient with a hypercholesteremia loses a large amount of cholesterol from the body. In the diet only animal sterols are omitted, as plant and vegetable sterols are not absorbed by human beings. Although the administration of thyroid is recommended, we have not observed any beneficial effect from its use. From the standpoint of prophylaxis it appears that when a member of a family manifests a disorder of cholesterol metabolism it may be wise for the rest of the family to follow a low cholesterol diet. When the diagnosis of xanthomatosis is made, the physician should investigate other members of the family.

SUMMARY

1 In the 6 cases of xanthomatosis with coronary artery disease in young adults that have been described there are three characteristic features: skin xanthomatosis, coronary insufficiency and hypercholesteremia.

2 A strong familial tendency is present and the disease often appears early in life.

3 Therapy consists of a diet low in animal cholesterol and other measures usually prescribed for patients with coronary artery disease. The familial occurrence affords an opportunity for the prophylactic institution of a low cholesterol diet in other members of the family as yet unaffected.

4 By recognizing and segregating this type of coronary artery disease we may anticipate a more hopeful therapeutic outlook than in patients with the usual coronary artery disease.

3875 Wilshire Boulevard

LEUKEMIA IN PREGNANCY

WITH REPORT OF A CASE

CAPTAIN WILLIAM C. MOLONEY
MEDICAL CORPS, ARMY OF THE UNITED STATES

ROY J. HEFFERNAN, MD
AND

S. CHARLES KASDON, MD
BOSTON

Leukemia is a rare complication of pregnancy. Forkner,¹ reviewing the literature up to 1938, found 53 cases reported and of these the diagnosis was questionable in 5 instances. Presenting 1 of their own. Grier and Richter² in 1939 were able to collect a total of 75 cases, but 13 of these were mentioned only bibliographically. We discovered another reported by Bentivoglio³ in 1936 which was not included in this series. From 1939 to the present writing there have been 2 additional cases reported in the foreign literature.⁴ These, with the 1 described here, bring the present total reported up to 79.

In our case chronic myelogenous leukemia was discovered early in pregnancy and undoubtedly preceded gestation. The disease was also complicated by pre-eclamptic toxemia. The mother was successfully delivered of a living normal child by cesarean section.

REPORT OF CASE

Mrs. H. M., aged 32, white, was first seen by her physician, Dr. Homer Brayton of Dorchester, Mass., Feb. 24, 1942. Her last period, following a normal menstrual cycle, began on Jan. 1, 1942. Physical examination revealed that the patient was poorly nourished, with a pale and sallow skin, a pulse rate of 84 and blood pressure 110/70. The heart and lungs were found to be normal, but palpation of the abdomen revealed a firm smooth mass, in the left upper quadrant, which extended to the iliac crest. The patient had discovered the mass but associated it with the possibility of pregnancy. She complained of several recent episodes of epistaxis, profuse night sweats and moderate weakness for two to three months preceding her first visit but otherwise had been in excellent health.

Blood examination revealed white blood cells 140,000, red blood cells 1,700,000, hemoglobin 45 per cent (Sahli), polymorphonuclear leukocytes 6 per cent, eosinophilic myelocytes 25 per cent, basophilic myelocytes 5 per cent, myelocytes 40 per cent, metamyelocytes 21 per cent, lymphocytes 3 per cent, blast cells 2 per cent and nucleated red blood cells 2 per cent. The red blood cells showed some achromia and some slight variation in size and shape, the platelets were normal. The Wassermann test was reported negative. A diagnosis of chronic myelogenous leukemia was made at this time. The patient received two small doses of 100 roentgens to the spleen on March 12 and a second on April 16. In May a definite diagnosis of pregnancy was established.

The antepartum course progressed normally until the thirtieth week, when signs of pre-eclamptic toxemia developed. The blood pressure rose to 140/90 and pitting edema of the ankles was noticed. She was placed on a salt free diet and advised to take additional rest, but by mid-September the blood pressure reached 150/90. She was confined to bed on a strict regimen, and two weeks later the pretibial edema had increased and the blood pressure had climbed to 180/110. A heavy trace of albumin was found in the urine. The patient was admitted to the Carney Hospital on September 16. The fundus was three

5. Jones, Burchenal, Jarmar.

fingerbreadths below the ensiform process with the vertex riding high. The fetal heart was heard in the left lower quadrant, rate 144. The spleen was palpable 12 cm below the costal margin in the left midclavicular line, smooth and slightly tender. The white blood count was 76,000. Two small hemorrhages were found in the left ocular fundus. These are commonly found in leukemia. A diagnostic roentgenogram of the

fetus demonstrated no fetal skeletal anomalies. As the pre-eclamptic toxemia had not responded to conservative measures it seemed advisable to terminate the pregnancy. As the cervix was long and firm, delivery by cesarean section was selected. On September 18, under spinal anesthesia (15 mg of pontocaine hydrochloride with 15 cc of dextrose) a transverse low cervical cesarean section was performed (R J H) and a normal premature female infant weighing 4 pounds 14 ounces (1928 Gm) was delivered. There was no difficulty with hemostasis, and the uterus responded excellently to intravenous ergonovine (0.0002 Gm) and hypodermic pitocin (10 cc). The immediate postpartum course (first twenty-four hours) was marked by a febrile response to 102.4 F, the pulse rose to 120 and massive drenching sweats occurred. Six hours after operation the patient passed approximately 300 cc of currant jelly clots vaginally but otherwise the recovery was uneventful. The changes in the blood are recorded in the accompanying chart (fig 1). Diethylstilbestrol in doses of 20 mg a day was used for suppression of lactation. It should be noted that the day after delivery the white blood count rose rapidly and the red blood count and hemoglobin fell. The spleen showed a relatively rapid increase in size during the first week post partum. Fifty roentgens over the spleen was administered on the eighth and tenth days and the blood picture improved definitely. The spleen decreased in size. Except for a small sterile collection of hemolyzed blood at the lower angle of the wound, which reabsorbed spontaneously, the incision healed normally. Examination of the placenta revealed an unusual number of immature white blood cells in the maternal lacunae, as shown in the photomicrographs (figs 2 and 3). The infant's blood count at birth was as follows: 25,000 white blood cells, 5,850,000 red blood cells, 126 per cent hemoglobin (Sahl), 65 per cent polymorphonuclear leukocytes, 15 per cent lymphocytes, 5 per cent eosinophils, 6 per cent myelocytes, 4 per cent band forms and 5 per cent nucleated red blood cells. Five days later the blood count showed 11,000 white blood cells, 5,560,000 red blood cells, hemoglobin 125 per cent (Sahl), 63 per cent polymorphonuclear leukocytes, 3 per cent myelocytes, 2 per cent eosinophils, 30 per cent lymphocytes, 2 per cent monocytes and 2 per cent nucleated red blood cells. These blood findings are within normal limits for a newborn infant in good general condition.

The patient was discharged from the hospital Oct 4, 1942 on the sixteenth day after delivery. The spleen was palpable 5 cm below the costal margin in the left midclavicular line. The blood count on discharge is reported in figure 1. The baby left the hospital on the sixteenth day in good condition weighing 5 pounds 5 ounces (2410 Gm).

The occurrence of amenorrhea is so common in the presence of leukemia that in this case the fact that conception had taken place was not known until the pregnancy was well advanced. Two small doses of x-ray therapy had the excellent effect of lowering the white blood cell count and elevating the hemoglobin and erythrocytes. Also the spleen was reduced in size so that no further x-ray therapy was deemed necessary after the fourth month of pregnancy.

The patient had a normal antepartum course until the seventh month, when signs of toxemia developed. This is apparently the only case of preeclamptic toxemia complicating leukemia in pregnancy reported thus far. Since the toxemia did not respond to conservative treatment and induction of labor through the pelvis was not considered feasible, cesarean section was elected.

Fig. 2.—Large leukemic cell in the maternal lacuna above the placental villus. Reduced from a photomicrograph with a magnification of $\times 100$ diameters.

In addition to our case three other leukemic mothers in the total series of 79 cases, were delivered by cesarean section.

1. Fleischmann² in 1923 did a cesarean section at the eighth month on a 30 year old tertiary. Her leukemia developed prior to gestation. The baby was stillborn and the mother died on the eleventh day post partum.

2 Thamer⁶ in 1925 sectioned a 28 year old secundipara in the eighth month. Her leukemia antedated pregnancy by five months. The infant was stillborn and the mother died eleven days post partum.

3 Hussy⁷ in 1934 delivered abdominally a 35 year old tertipara who developed leukemia during pregnancy. The section was done at seven and one-half months and, although the infant survived, the mother died twenty-four hours after delivery.

The case described by us would seem, therefore, to be the first thus far reported in which a pregnancy complicated by leukemia was successfully terminated by cesarean section. In keeping with the experience of other authors, hemostasis was easily obtained during the operative procedure and postpartum hemorrhage did not occur.

Fig. 3—Several large leukemic cells. The tip of a placental villus in the right lower corner. Reduced from a photomicrograph with a magnification of 2,100 diameters.

Contrary to the statement of Herrnberger,⁸ a rise rather than a fall in white blood count occurs immediately after delivery. Not only is this borne out in this case, but in Herrnberger's own reported case there occurred a sharp rise in the white blood cell count immediately following the termination of pregnancy. Chronic lymphatic leukemia has been reported only once in pregnancy. As Vignes⁹ pointed out, this probably is due to the tendency of the lymphatic cells to infiltrate the adnexa, precluding the possibility of conception. On the other hand, acute lymphogenous leukemia has been reported not infrequently.

COMMENT

The progress of this case substantiates the opinions of Grier and Richter² that a patient who becomes pregnant early in the course of chronic myelogenous leukemia will usually give birth to a living infant and that in 4 out of 5 instances she will survive the delivery. Folkner¹ also believes that pregnancy does not accelerate the course of chronic leukemia. In our case the leukemic process tended to regress during pregnancy.

The occurrence of leukemia in pregnancy tends to shed some light on the etiology of the morbid process. It is significant that a leukemic mother has never given birth to an infant with leukemia. It has been postulated that a chemical or hormonal factor may be responsible for leukemic stimulation of the hemopoietic tissue. However, it is evident that either such a substance does not exist or it is incapable of passing the placental barrier. Moreover, in experimental studies Burchenal¹⁰ has found it impossible to transmit leukemia of mice to the fetus by inoculation of the mother. Jarman¹¹ found it possible to inoculate chick embryos with a transmissible virus of chicken leukemia. This suggests that fundamentally, the development of leukemia must be dependent on a specific tissue susceptibility.

TREATMENT

It is our impression that pregnancy has apparently no effect on the progress of leukemia. The natural history of this disease is such that the outcome is relatively uninfluenced by treatment although the patient may be symptomatically improved. At present there is no effective treatment for the individual with acute leukemia, pregnant or otherwise. Since leukemia in pregnancy is such a rare disorder, no one has had sufficient personal experience to outline specifically the management of this complication of pregnancy. It seems obvious, however, that sterilization of the leukemic woman or interruption of pregnancy is not advisable. The palliative use of x-ray therapy for chronic myelogenous leukemia in pregnancy should not be withheld. It is possible to irradiate the long bones, the thorax and with due care even the spleen with no deleterious effect to the fetus in utero. The intravenous or oral use of radioactive phosphorus would seem contraindicated because of the direct action on the uterus and its contents. Solution of potassium arsenite, although its value is questioned by some clinicians, can be used without endangering the fetus. Whole blood transfusions are indicated when anemia and thrombocytopenia with attending hemorrhagic tendencies manifest themselves. In the management of the pregnancy the presence of strictly obstetric complications such as cephalopelvic disproportion, toxemia and placenta previa can be controlled on their obstetric indications. In the case reported the preeclamptic toxemia was treated as it would have been without the presence of leukemia.

SUMMARY AND CONCLUSIONS

1. Leukemia complicating pregnancy is a rare entity, a total of 79 cases have been reported.
2. The natural course of leukemia is apparently uninfluenced by gestation. Leukemia per se is therefore not an indication for the interruption of pregnancy.
3. Chronic leukemia in pregnancy is a problem which can be intelligently handled in the majority of cases only by the combined efforts of the hematologist and the obstetrician.

POSTOPERATIVE FOCAL, NONSEPTIC NECROSIS OF VERTEBRAL AND CEREBELLAR ARTERIES

WITH RUPTURE AND SUBARACHNOID
HEMORRHAGE

JAMES W. KERNOHAN, M.D.
AND

HENRY W. WOLTMAN, M.D.
LOCHESTER, MINN.

Subarachnoid hemorrhage caused by focal nonseptic necrosis of the vertebral artery or of its branch, the posterior inferior cerebellar artery is an unusual occurrence. We here record our observations made on 4 elderly, generally slightly hypertensive patients who showed no evidence of endocarditis or of a general or local infectious process who died of this condition within a few days of uncomplicated abdominal operations. Only the apparently relevant features of the histories and examinations are given.

There is a voluminous literature on the subject of subarachnoid hemorrhage however much of this is in reference to ruptured congenital aneurysms. Sands¹ in a recent study of subarachnoid hemorrhage reported 120 cases and pointed out that it is caused by (1) trauma, (2) arteriosclerotic degeneration of vessel walls, (3) septic or infectious emboli (4) ruptured intracranial aneurysms (5) massive cerebral hemorrhage invading the subarachnoid space (6) intraventricular hemorrhage (7) blood dyscrasias and (8) ruptured vascular neoplasm. In addition to the foregoing there is a relatively large group which Sands listed as of "unknown or undetermined cause."

Necrosis of the arteries of the brain is a well known phenomenon in large infarcts and we have also seen extensive necrosis of meningeal blood vessels in many cases of tuberculous meningitis or septic meningitis as well as in cases of "periarteritis nodosa," septic endocarditis and other conditions but we have not seen any of these that had vessels ruptured and produced extensive subarachnoid hemorrhage. As a rule in such cases the entire wall of a small artery becomes necrotic and not a small segment of the circumference leaving the remaining portion of the wall normal. Winternitz and LeCompte² produced varying degrees of inflammation and proliferation of the walls of arteries by injecting organisms of different degrees of virulence into the walls of arteries but did not produce areas of focal necrosis. We have been unable to find any record in the available literature of a case of subarachnoid hemorrhage due to rupture of a noninflammatory necrotic focus in the wall of a cerebral artery.

REPORT OF CASES

CASE 1—An educator aged 62 was registered at the Mayo Clinic on Feb. 2, 1942 for a general examination and consideration of a right inguinal hernia. Examination disclosed a systolic blood pressure of 160 mm. of mercury and a diastolic pressure of 100 mm. There were slight hypertensive sclerosis of the retinal arterioles and slight sclerosis of the choroidal vessels. An apparently old retinal detachment was noted in the lower temporal sector on the right. Bilateral direct inguinal hernias

were present. Numerous leukocytes were noted in the prostatic secretion. An occasional erythrocyte was found in the urine. Cystoscopic examination gave negative results.

On February 24, with the patient under spinal anesthesia, both inguinal hernias were repaired. On February 28 he complained of an occipital headache, vomited, became confused, had a convulsion and died.

At necropsy the recent operative incision had the usual appearance of a wound four days old. The heart was hypertrophied and weighed 505 Gm., in contrast to an estimated normal weight of 370 Gm. The arteriosclerosis of the aorta was estimated as grade 1+ (on a basis of 1 to 4, in which 1 designates the least and 4 the greatest degree of arteriosclerosis) and the other large systemic arteries were graded similarly. The prostate was slightly enlarged, but there were no other findings of any significance aside from those of the central nervous system.

There was extensive subarachnoid hemorrhage. We estimated the extravasated blood at about 200 cc., it had completely filled the subarachnoid space and some had extended into the ventricles. After removing much of the blood we found that there was arteriosclerosis of the cerebral vessels.

FIG. 1—Basilar, vertebral and posterior inferior cerebellar arteries. The arrow indicates the point of rupture in the left posterior inferior cerebellar artery. The defect was in the anterior aspect of the vessel wall.

graded 2+ that there was no aneurysm of the vessels arising from the carotid arteries and that the circle of Willis did not show any abnormalities. There were symmetrical fusiform dilatations of the vertebral arteries about 0.5 cm. above their entrance into the cranial cavity; these dilatations were each 1 cm. long. The vertebral arteries had become normal about 3 cm. before fusing to form the basilar artery. After removing more blood we found a small hole about 1 mm. in diameter in the left posterior inferior cerebellar artery 1.5 cm. from its origin at the left vertebral artery (fig. 1). There was no branch of the artery at the site of perforation and the artery seemed normal proximal and distal to the defect (there was no dilatation or aneurysm). The other arteries in the posterior fossa were normal.

Microscopic sections were prepared from many of the cerebral and cerebellar vessels as well as from many vessels of other organs. These sections were stained with hematoxylin and eosin, van Gieson, Weigert elastin and elastin H stains as well as Giemsa, Brown, Gram, mucicarmum and cresyl violet. Except for some arteriosclerotic changes of a minor degree all vessels were normal. However, sections of the left posterior

² Winternitz, M. C. and LeCompte, P. M. Experimental Infectious Angitis. Am. J. Path. 16: 112 (Jan.) 1940.

inferior cerebellar artery at the site of the rupture showed a small region of complete necrosis of the vessel wall. This region of necrosis included only a quarter of its circumference. The necrotic focus was wider at the adventitia than in the media, while the internal elastic lamina had curved outward, lining the inner third of the side of the defect (fig 2). There was no inflammatory reaction in the media or intima (fig 3),

Fig. 2—The edge of the defect in the arterial wall showing the inflammatory reaction in the adventitia and the absence of inflammation in the media and intima (crystal H stain, $\times 160$)

but where the necrosis had involved the adventitia beyond the defect in the wall were many polymorphonuclear leukocytes. In figures 2 and 3 can be seen the extent of necrosis along the adventitia of the vessel. There was no evidence of any inflammatory or infectious material in the lumen, intima or media of the artery. Bacteriologic stains did not show any organisms anywhere in or around the wall or in the necrotic portion of the adventitia of this blood vessel.

CASE 2—A housewife aged 62 was registered on May 22, 1941 as a patient at the Mayo Clinic with the complaint of epigastric distress of several years' duration. Roentgenograms disclosed a duodenal ulcer. The blood pressure was 172 mm of mercury systolic and 110 mm diastolic. The retinal arterioles were slightly narrowed and sclerotic, chronic hypertensive type, and the choroidal vessels were slightly sclerosed. Urea in the blood was reported as 32 mg per hundred cubic centimeters.

On May 30, 1941, with the patient under inhalation anesthesia with ethylene, oxygen, carbon dioxide and ether, posterior gastroenterostomy was performed because of two subacute ulcers on the posterior wall of the duodenum.

Two days after operation the patient complained of pain in her head and became stuporous. The pupils were pinpoint, the neck was not rigid and Babinski's sign was positive on the left. The patient died thirty minutes after the onset of the headache.

At necropsy the recent operative site showed signs of healing, and there was a chronic duodenal ulcer with evidences of many healed ulcers (scars) and partial obstruction of the lumen of the duodenum. There was some pancreatitis but no fat necrosis. The remainder of the general examination gave essentially negative results except for hypertrophy of the heart, which weighed 365 Gm in contrast to an estimated normal of 275 Gm. There was arteriosclerosis of the aorta and larger arteries graded 2 on a basis of 1 to 4.

Examination of the brain revealed the subarachnoid space to be filled with blood and blood clots. The arteriosclerosis of the main arteries at the base of the brain was graded 1 on a basis of 1 to 4. There were no anomalies or aneurysms of

the circle of Willis or of the basilar or vertebral arteries. In searching for a source of the subarachnoid hemorrhage a hole 1.5 mm in diameter was found in the left posterior inferior cerebellar artery less than 1 cm from its origin from the left vertebral artery.

The results of microscopic examination of the rupture in the artery were identical with those in the previous case. The necrosis extended beyond the defect in the adventitia, the media was free from inflammation or edema and the elastic tissue of the intima followed the defects outward partly across the media. There was no inflammatory reaction anywhere, except some polymorphonuclear leukocytes in the necrotic tissue of the adventitia. No organisms were found after the use of the Brown Gram stain. The other arteries of the brain were normal. Examination of many sections of the pancreas did not show any necrosis of the pancreatic arteries as a possible explanation of the interstitial pancreatitis, which was both acute and chronic.

CASE 3—A fruit pedler aged 54 came to the Mayo Clinic on June 25, 1941 because of bilateral inguinal and umbilical hernias. The left inguinal hernia had been operated on three times previously. The patient had recovered from rhinitis a few weeks previously. In addition to the hernias, examination disclosed a systolic blood pressure of 176 mm of mercury and a diastolic pressure of 108 mm. There were minimal narrowing and sclerosis of the retinal arterioles. The tonsils were regarded as a possible focus. The left testicle was atrophied. The leukocytes numbered 15,000 per cubic millimeter of blood. There was a trace of albumin in the urine.

On July 1, with the patient under spinal anesthesia, the left testicle was removed and a hernial opening the size of the hand was closed. Hemorrhaphy was also performed for recurrent umbilical and epigastric hernias.

On the day following the operation, the patient suddenly gasped for breath and died.

The general examination did not reveal anything of significance, the operative wounds were such as one would expect one day after operation. The heart was slightly hypertrophied, weighing 348 Gm in contrast to an estimated normal of

Fig. 3—The inflammatory reaction to the necrosis in the adventitia. Note the necrosis extending into the adventitia beyond the edge of the hole. Also note the absence of other inflammatory reaction (hematoxylin and eosin stain $\times 85$)

300 Gm. There was also arteriosclerosis of the aorta, coronary and other arteries, graded 2 on a basis of 1 to 4.

Examination of the brain showed a massive subarachnoid hemorrhage which had extended into the ventricles. The circle of Willis and the vessels derived from it were normal except for arteriosclerosis graded 1. There were small symmetrical dilations of both vertebral arteries 1.5 cm proximal to the

union to form the basilar artery. There was a small hole about 1 mm in diameter at the lower margin of the small dilatation of the left vertebral artery. Microscopic examination of the right vertebral artery showed that it was normal even the dilatation represented a slight thinning of the wall, but it was not on the basis of arteriosclerosis. The defect in the left vertebral artery was identical with the defects described

Fig 4—A small necrotic focus in the wall of the artery involving the adventitia and outer fourth of the media. No vasa vasorum are present and there is no inflammation in the inner three fourths of the media or the intima (hematoxylin and eosin stain, X 160).

in the posterior inferior cerebellar arteries in cases 1 and 2. In addition, several millimeters below and opposite the defect we found a region of necrosis which included the adventitia and the outer quarter of the media. The inner three fourths of the media and the intima beneath this small region of necrosis were normal. This necrotic focus was partly infiltrated with polymorphonuclear leukocytes (fig 4). There was no inflammation or thrombus in or beneath the intima opposite this focus. This was the only lesion which we found on any blood vessel—cerebral or systemic, and the posterior inferior cerebellar arteries were normal. We were unable to identify the vasa vasorum in this region of acute degeneration, although in the adventitia of the vertebral artery around it we identified the vasa vasorum as normal. Examination by means of the Brown Gram stains failed to reveal any organisms.

CASE 4—A truck driver aged 55 was registered first on Aug 13, 1928 because of attacks of abdominal pain which had been present for a year and a half and which were suggestive of cholecystitis. The blood pressure was 130 mm systolic and 80 mm diastolic. Analysis of gastric contents showed a value for total acids of 18 and for free hydrochloric acid of 0. A diagnosis was made of cholecystitis probably associated with stones. On August 20 exploration revealed chronic catarrhal cholecystitis with cholelithiasis, and cholecystectomy and appendectomy were performed.

The patient returned on March 21, 1932 because of flatulence. Fractional analysis of gastric contents after a test meal showed a value for total acids of 4 and for free hydrochloric acid of 0. Roentgenograms of the stomach were negative. The systolic blood pressure was 120 mm of mercury and the diastolic pressure 80 mm.

The patient was registered the third time on June 1, 1942. He reported that he had been quite well until a year previously but that since then he had had occasional pain in the right hypochondriac region similar to the pains he had experienced before the operation, and that he was troubled with gas and constipation and had lost 30 pounds (13.6 Kg). The systolic blood pressure was 132 mm of mercury and the diastolic pressure 80. Fractional analysis after a test meal showed a

value for total acids of 8 and for free hydrochloric acid of 0. Roentgenograms of the stomach showed a carcinoma of the pyloric half of the stomach.

On June 4, with the patient under nitrous oxide, carbon dioxide, oxygen and ether anesthesia, exploration was performed and carcinoma of the stomach with perforation into the transverse mesocolon was found. Partial gastrectomy, of the anterior Baltour Polva type, with enteroanastomosis, partial duodenectomy and exteriorization of a devitalized segment of the transverse colon was done. Microscopic studies of the posterior wall of the lesser curvature disclosed a grade 4 flat ulcerating carcinoma 8 cm in diameter by 1 cm in depth with extension into the serosa and beginning infiltration of the mesentery and involvement of one lymph node.

Following the operation the patient spoke of having a mild headache. On June 7 at 5:20 p.m., while talking to his wife, he suddenly lost consciousness, and the eyes turned upward and toward the right. Within ten minutes it was observed that the left arm and leg remained motionless. The neck was somewhat rigid and both plantar responses were slightly extensor. The systolic blood pressure was 210 mm of mercury and the diastolic pressure 100. Two hours later the patient was more responsive. The temperature had risen to 105°F. On June 8 and 9 he improved considerably and his headache was less severe but he remained somewhat confused. On June 10 at 2:40 p.m. the patient again complained of severe pain in his head, lost consciousness and at 3 p.m. died.

Necropsy showed healing of the operative wounds and there was no residual carcinoma or evidence of inflammation. The heart was hypertrophied and weighed 383 Gm. in contrast to an estimated normal of 300 Gm. There was arteriosclerosis of the aorta graded 1 and of the coronary arteries graded 2, on a basis of 1 to 4. There were no other findings of any significance in the general necropsy.

Fig 5—The edge of a necrotic but nonruptured focus. Except for the fact that it has not ruptured it is similar to the lesions in the foregoing cases (hematoxylin and eosin, X 100).

Examination of the brain revealed a massive subarachnoid hemorrhage but none was present in the ventricles. There was arteriosclerosis of the larger cerebral arteries graded 1 on a basis of 1 to 4. There were no aneurysms or anomalies of the blood vessels composing or derived from the circle of Willis. There was a small focus about 1.5 mm in diameter in the right vertebral artery 5 mm above the origin of the

right posterior inferior cerebellar artery, this ruptured vessel was evidently the source of the subarachnoid hemorrhage. There was no hemorrhage in the substance of the brain in this case or in any of the preceding ones. The other arteries of the posterior fossa were normal.

Microscopic examination of many of the cerebral arteries showed that all were normal except the right vertebral artery. Sections through the site of rupture revealed the fact that it was identical with the defects in the ruptured arteries of the other three cases—namely, necrosis with localized inflammatory reaction of the adventitia, a truncated defect in the media with no evidence of necrosis at the edge of the hole and the internal elastic lamina curving outward, through the inner half of the defect. As in previous cases there was no inflammation in media or intima even at the edge of the rupture. In the arterial wall opposite the rupture was a truncated region of necrosis with the broader base at the adventitia and the narrower apex at the intima (fig. 5). The internal elastic lamina was not ruptured but was swollen and appeared to be undergoing early necrosis or degeneration (fig. 6). There were a few polymorphonuclear leukocytes present between the elastic and the endothelium of the intima. The endothelium was intact beneath this focus of necrosis except at one place, where it had disappeared, and blood was escaping from the lumen of the

Fig. 6—The swollen degenerating intimal elastic lamina opposite the focus of necrosis in the arterial wall (elastin H, X 105)

artery into the wall of the vessel and was burrowing between the outer portion of the media and the adventitia, which was almost completely necrotic. This blood between the media and the adventitia had the appearance of an early dissecting aneurysm. The endothelium of the intima was otherwise intact and so there was no mural thrombus.

There were several smaller foci of necrosis which varied much in size and depth, some included only the adventitia and others extended varying depths into the media, but there was only one focus which extended to the intima. These smaller foci, if deep, were wedge shaped but, if superficial, were elliptic with their base in the adventitia, and the concave portion extended deepest into the media. Most of these foci were quite recent, since there was no cell reaction in the media. In most foci the only reaction was in the adventitia, and there it was represented by some polymorphonuclear leukocytes, there were no lymphocytes in or around these small necrotic regions. In two places erythrocytes had replaced the media of the arterial wall, only the intima and the adventitia remaining intact, but there was no necrosis or cell reaction at these intramural hemorrhages, which simulated early dissecting aneurysms. The source of the blood could not be found and the intima was intact. Bacteriologic stains failed to reveal any organisms in any of these foci of necrosis.

There was no obvious explanation of the foci of necrosis and the small intramural hemorrhages. The vasa vasorum were normal in the adventitia of the artery except at the foci of necrosis, where we could not see any vasa vasorum. They were obliterated, but whether this obliteration was the cause or the result of the necrosis was impossible to determine—the necrosis had destroyed the evidence. It was possible that the regions of necrosis were small infarcts, the result of an occlusion of the vasa vasorum. It was also possible that the initial lesion was a small intramural hemorrhage followed by necrosis of the wall, or a third possibility was necrosis as the result of occluded vasa vasorum followed by hemorrhages. Either one alone, or the combination of two, could have been responsible, and since there was no blood pigment in any necrotic region we think that hemorrhage was not the primary factor. Arteriosclerosis was present only to a minor degree in this as in the other 3 cases, so we think that the necrosis was not on the basis of arteriosclerosis.

COMMENT

We were at a loss to find some common denominator to explain the focal necrosis in the walls of a cerebellar artery as the source of the subarachnoid hemorrhage in the foregoing 4 cases. In all 4 cases there was some evidence of elevation of blood pressure with slight cardiac hypertrophy and, in all, uncomplicated surgical operations had been performed. These are common findings and the foregoing complication is rare. There was no other finding common to all 4 cases. We have been unable to find a previously reported case, but it is possible that similar cases have been included in the past in the group of cases of spontaneous subarachnoid hemorrhage designated by Sands as of "unknown or undetermined cause." It seemed strange to us that we should encounter four such postoperative complications in one year. We examined anew our previously collected cases of unexplained subarachnoid hemorrhage but failed to find any lesion or rupture of any vertebral or posterior inferior cerebellar artery. The cause of the necrosis is undetermined and we have been unable to relate it to the surgical procedures, anesthetic or medication before or after operation.

General arteriosclerosis was not advanced in any of the cases in spite of the age and evidence of hypertension in all 4 patients, while the arteriosclerosis of the cerebral arteries was even less severe than of the systemic arteries. The arteriosclerosis was minimal in the vertebral and posterior inferior cerebellar arteries, and this was confirmed by microscopic examination. There was no evidence of a mycotic aneurysm at the sites of the ruptures, moreover, there was no source from which an infected embolus could arise and the ruptures were not at the origin of a branch in any of the arteries. There was no elevation of temperature before or after the operations. Bacteriologic studies of histologic preparations of the lesions gave negative results. There was no evidence of an infectious process in the organs in general, except in the second case, in which there was interstitial pancreatitis, however, there was no hemorrhage into the pancreas and we were unable to find acute degenerative changes in its blood vessels. The lesions in the walls of the arteries in these cases did not simulate the changes seen in periarteritis nodosa, since the necrosis seemed to start in the adventitia rather than in the media, they were limited to one artery in each case and there was little periarterial inflammation and no intimal reaction. The points of rupture were unlike those of an atheromatous plaque, there was acute degeneration and not a chronic degenerative process such as is seen in atheromatous lesions. In 1 case there

were slight bulgings of the vertebral arteries, but these were not the result of atheromatous weakening of the wall of the arteries and such bulging of the vertebral arteries is seen fairly commonly at necropsy of elderly patients.

Little information could be obtained as to the nature of the process in the first 2 cases but in case 3 and particularly in case 4 we found in the wall adjacent to the rupture early and unruptured foci of necrosis. These foci seemed to have their origin in the adventitia of the artery and in some the necrosis had extended into the media while in one rather large focus of necrosis it extended down to the intima and even the internal elastic lamina showed evidence of early degeneration. This was a truncated region of necrosis with the base in the adventitia. These smaller foci of necrosis—shallow and deep—suggested to us regions of infarction. In recent years there have been some excellent studies of the blood vessels of the central nervous system and changes with age by Baker,² Cobb and Blam,³ Hackel,⁴ Thomas, Ranke,⁵ and others but there was no mention of necrosis or of the blood supply of the walls of these vessels. Even Wintermiz, Thomas and LeCompte⁶ did not describe vasa vasorum in the cerebral arteries. Our own studies showed us that vasa vasorum are normally present in the walls of vertebral arteries but what would be the result of occlusion of one or more of these is simply conjecture. It is possible that an infarct of the wall of the artery would follow and the foregoing lesions simulate infarcts. We do not have any direct evidence that there was an occlusion of any of these vasa vasorum prior to the degeneration of the wall but these small vessels were not patent in the regions of necrosis at the time of our examination. Occlusion of the vasa vasorum of any vessel is probably a rare occurrence, however it is possible for this to occur as the result of rapid lowering of blood pressure.

SUMMARY

In 4 cases focal necrosis occurred in either the posterior interior cerebellar arteries (2 cases) or in one vertebral artery (right 1 case left 1 case) following comparatively simple uncomplicated abdominal operations. The foci of necrosis had ruptured and led to massive subarachnoid hemorrhage. We have been unable to find records of similar cases in the available literature but suggest that in some cases subarachnoid hemorrhage of undetermined origin might possibly have had its origin in a manner similar to that of the foregoing cases. We have considered various possible causes for the foci of necrosis starting in the walls of these vertebral vessels and have suggested that they might represent focal infarcts of the walls of the arteries. Some future work on the blood supply of the walls of the vertebral arteries and the vasa vasorum of these vessels remains to be done before an answer to such a hypothesis is obtained.

THE TREATMENT OF PNEUMOCOCCIC PYARTHROSIS

M. A. BLANKENHORN, M.D.

AND

EDA GRUPEL, B.S.
CINCINNATI

Our purpose in writing this paper is to present in summary the records of an unusual number of patients with pneumococcic pyarthrosis treated conservatively rather than by conventional surgical methods. The patients 11 in number, were all seen in the Cincinnati General Hospital and studied in the pneumonia laboratory of the department of medicine.

INCIDENCE

Purulent arthritis is generally regarded as 'a rare and grave complication of pneumonia'.¹ It was found by Fabian² in 1910 once among 195 cases of lobar pneumonia at autopsy. Bulkley³ in 1914 collected from the foreign and American literature records of incidence of about 0.1 per cent in pneumonia. Cecil⁴ at Bellevue Hospital recorded from 1926 to 1932 an incidence of 0.6 per cent among typed pneumonia cases. Schiff⁵ reported from the Cincinnati General Hospital an incidence of 0.5 per cent in the years 1924 to 1929 among 629 cases.

Our present series from 1935 to 1942 inclusive shows an incidence of 0.4 per cent, or 9 cases among 2,322 of typed pneumonia in adults.

Pneumococcic pyarthrosis may occur independent of pneumonia especially among children. Two such cases are reported here by courtesy of the department of pediatrics but the bacteriologic study was done in the pneumonia laboratory of the department of medicine.

One must relate pyarthrosis of pneumonia to the bacteremic state, therefore any hospital service receiving late cases or cases of unusual illness will find an increased incidence of septic complications. We are unable to relate the rather high incidence to any other factor especially specific treatment or exceptional accuracy of diagnosis.

This report is written mainly to record the effects of specific treatment in this 'grave' complication of pneumonia.

DIAGNOSIS

In every case of the 11 here reported the pneumococcus was recovered from the blood or from the joint. In 7 instances the organism was recovered from the blood and the joint simultaneously. In 2 instances (cases 7 and 9) we discovered pyarthrosis by aspirating the affected joint of a patient ill with lobar pneumonia and pneumococcemia but cultures of material taken from the joints were negative. We think that this circumstance of negative cultures is not against our diagnosis because drug treatment was well under way when joint cultures were made and in 1 instance para-aminobenzoic acid was not used in the culture mediums.

This work was aided by a grant from the Lederle Laboratories, Inc. From the Department of Internal Medicine of the University of Cincinnati and the Cincinnati General Hospital.

The diagnosis was usually made at once by finding all the signs and symptoms of acute painful involvement of one or two large joints. In 1 instance (case 10) pneumonia was not even suspected, while in another (case 8) pneumonia was suspected but not proved. When pneumonia is not apparent, the disease must be differentiated from gonorrheal arthritis, to which it is very similar. The differentiation should be made easily if cultures are well managed before the sulfonamides are given. In the main, the pneumococcus is usually grown without much difficulty and the identification made easy by the technic of "typing." Migrating polyarthritis such as that of rheumatic fever was not seen in our experience, nor have we found it described with laboratory proof. Pneumonia due to pneumococci is not rare as a complication of rheumatic polyarthritis. The polyarthritis of serum sickness is well known and easily differentiated from pneumococcal pyarthrosis, it generally resembles rheumatic fever. X-ray studies in our series were of value mainly to exclude osteomyelitis or periostitis. The cases reported here were all so examined and nothing was shown other than slight demineralization of bone and swelling of soft parts. Destruction of cartilage did not occur or else was not shown by x-ray examination or by the functional results at discharge.

In 8 instances there was a single joint involved and in 3 there were two, but there were never more than two. The knee and ankle were most commonly involved. The disease as described in this short series is not different in any way from the usual textbook description except that it has been treated with specifics and therefore has become mild and of short duration. In case 1 pericarditis accompanied pyarthrosis, and meningitis also in case 2. No other suppurating lesion was noted as coincidental. Pneumococcal endocarditis has been found at the Cincinnati General Hospital at autopsy in 39 cases from 1935 to 1942 among typed cases of pneumonia, but only once was there associated pyarthrosis.

TREATMENT

Our treatment has been altogether conservative in that we have relied on specific drugs or serum or the two together with repeated aspirations and the use of splints.

We would not suggest abandoning well established principles of surgical treatment on so little evidence as these few cases present. We have done with pyarthrosis what we are doing with pneumococcal hydrothorax, namely, to depend on specifics and on early tapping for drainage while watching the patient as a whole, i. e. taking daily blood cultures and making frequent examinations for new foci of suppuration and for intoxication by the drug employed. With specific treatment there is little danger of a recurrence of pneumococcemia if the purulent focus is improving. This is consistent with the present concept of the action of the sulfonamides. Such management provides a maximum of the drug that is bacteriostatic and drains the local area where inhibiting substances may develop from tissue necrosis or abscess.

In case 4 incision and drainage were employed together with serum, this being in 1937 before the sulfonamides were used. Our series is arranged chronologically from 1936 to 1942 to represent the progressive change from the usual surgical incision and drainage to the use of serum and sulfonamides as they became available.

Patient 2 received no treatment because she was considered, at the age of 90, too old to be given serum, this being in 1936. Patient 3 was untreated because he came too late for specific treatment as given in 1937.

The decisions about drainage or tapping were easily made by following the principle of tapping for diagnosis as soon as the disease was suspected and continuing to tap to provide drainage as often as any fluid reaccumulated. Splints were used to immobilize the joints as long as there was fever.

Sulfathiazole was used oftener than other sulfonamides. Serum alone was used five times. In only 2 cases did we use combined drug and serum therapy. In but 1 instance did we use agglutination tests or skin tests to decide matters of dosage. We were guided by temperature and local signs mainly. Theoretically, serum and a sulfonamide compound should be used together as in the treatment of influenzal meningitis, but our series does not suggest such a method to be superior. We think that serum should be given to any patient who is not doing well with the drug alone or who has a positive blood culture late in the course of pneumonia.

The complication of pyarthrosis seemed to prolong the fever of pneumonia in several instances but usually it did not. We have one example of delayed resolution but not beyond such delay as might occur in uncomplicated pneumonia. Pyarthrosis unassociated with pneumonia when treated with drugs responds in about the same manner as does gonococcal arthritis.

RESULTS

Three of the 11 patients died, 2 were given no treatment for the reasons stated and 1 must be regarded as having had too little serum (80,000 units of horse serum in case 1) and no drug because there was none.

In the usual sense of assessing specific treatment, there was no treatment failure. This we think noteworthy because the usual prognosis has been "always grave."

Bulkley in 1914 found from the collected literature a fatality rate of 24 per cent for single joint involvement and 72 per cent for multiple. We think the fatality rate should be that of uncomplicated pneumonia.

During the acute stage of the disease all the cases were seen by consultants from orthopedic or surgical services, who concurred in our form of treatment except in case 4, which was treated by surgeons. Physical therapy was not needed to bring the joints back to normal function except in one instance (case 4).

A follow-up study of these cases shows perfect functional results except in case 4 treated with incision and drainage. This knee seventeen months later showed good function for ordinary work but with some limitation of motion.

Cases are reported briefly herewith.

REPORT OF CASES

CASE 1—L. B., a Negro aged 35, was admitted on the fifth day of his disease with bilateral lobular pneumonia due to pneumococcus type II. The white blood cell count was above 34,000 and blood culture was sterile. On the second hospital day and the fifth day of arthritis 5 cc. of purulent fluid which yielded pneumococcus type II was aspirated from his elbow. An insufficient amount (80,000 units) of horse serum was administered the fourth hospital day with a subsequent temperature drop to 99 F., but death occurred four days later. Permission for autopsy was not granted, but acute pericarditis seemed quite likely. Blood cultures remained negative.

CASE 2—A. B., a Negro woman aged 90, was admitted with bacteremia and with arthritis of fourteen days' duration and

lobar pneumonia of three days' duration both due to pneumococcus type XI. The white blood cell count was 11,900. Aspiration from her knee yielded 30 cc of purulent fluid containing pneumococcus type XI on the second hospital day. She received no specific therapy because of her age and died on the third hospital day with bacteremia, meningitis and endocarditis, confirmed by autopsy.

CASE 3—D W, a white man aged 41 with pneumonia of the left lower lobe due to pneumococcus type V, was admitted with bacteremia and signs of endocarditis on the fifth day of his disease. On seven occasions his blood culture was positive for pneumococcus type V. The knee and acromioclavicular joints were aspirated on the tenth day yielding 70 cc and 5 cc respectively of fluid which was purulent and yielded pneumococcus type V on culture. No specific was used for treatment because of the advanced stage of his disease. The temperature remained above 102 F, the white blood cell count was above 120,000 and he died probably of endocarditis on the eleventh hospital day. Permission for autopsy was not obtained.

CASE 4—H I, a white man aged 39 with pneumonia of the right upper lobe due to pneumococcus type I was admitted with pneumococcal bacteremia on the fourth day of the disease. Eighty cc of purulent fluid was removed from the knee on the second hospital day and 70 cc was removed on the third hospital day. Cultures yielded pneumococcus type I. He received a total of 120,000 units of horse serum and on the fifth day the joint was drained of 250 cc of thick creamy pus and then irrigated. Culture of this pus again revealed pneumococcus type I. The white blood cell count up to the tenth day remained above 23,000 but his temperature gradually fell from that of 105 F on admission to normal when discharged as entirely recovered on the eighteenth day.

CASE 5—J J, a Negro girl aged 16 months, entered with pneumonia of the right upper lobe due to pneumococcus type VI. On the fourth hospital day (the sixth day of disease) 15 cc of purulent fluid obtained from her ankle contained pneumococcus type VI. A subsequent tap was also positive. She had two positive blood cultures subsequent to her initial joint aspiration. Treatment consisted of 1,250 units of pneumococcus type VI serum and irrigation and drainage with a cast applied on the fifth day. Blood culture was negative when taken three days later. The white blood cell count of 23,100 and the elevated temperature gradually fell to normal whereupon she was discharged as recovered on her twentieth hospital day.

CASE 6—R T, a white boy aged 4 years, was admitted with bronchopneumonia of two weeks' duration and arthritis of four days' duration due to pneumococcus type VI. This followed an attack of pertussis. His white blood cell count was 38,500, temperature was 104 F and blood culture was positive for pneumococcus type VI. Four cc of purulent exudate was aspirated from the ankle on the second hospital day, 2 cc of thin, bloody fluid on the sixth day and 2 cc of yellow pus on the eighth day. Cultures of each grew pneumococcus type VI. He received a total of 92,500 units of serum on the third and fourth days. He responded to the serum so that his temperature gradually fell to normal. After a few days of serum sickness he was discharged as recovered.

CASE 7—J W, a Negro aged 37, entered with pneumonia of the left lower lobe of one day's duration due to pneumococcus type VIII. Only the admission blood culture was positive. The knee was aspirated of 20 cc of yellow-green fluid twice but cultures were sterile. Twelve Gm of sulfamethylthiazole was administered each day for six days. The drug level in the blood ranged above 4 mg per hundred cubic centimeters and the white blood cell count between 5,000 and 16,000. Gradually his temperature fell to normal, and he was discharged on the twentieth day.

CASE 8—T R, a white man aged 66, entered with a gastric complaint due to a malignant growth and hematemesis. After several transfusions he was found on the eighteenth day to have arthritis of the knee. His blood stream was sterile but 2 cc of amber colored fluid obtained from the knee yielded pneumococcus type III. Subsequent taps yielded 60 cc and 30 cc of cloudy yellow fluid, which was sterile. A total of 26 Gm of sulfapyridine was given over a period of seven days with a subsequent fall in temperature and recovery of the knee.

CASE 9—O S, a Negro aged 37, was admitted with pneumonia of the right lower lobe of seven days' duration and bacteremia due to pneumococcus type V. The bacteremia, present on admission, cleared promptly, but on the fourth day arthritis developed. Cultures of 30 cc of moderately thick yellow fluid aspirated from the knee and 2 cc of thick pyosanguineous exudate from a sternoclavicular joint were sterile. He received 200,000 units of pneumococcus type V serum on the second hospital day, he first received sulapirazine and then sulfathiazole in doses of 6 Gm a day until two days before discharge. He maintained an average blood level of 2 mg per hundred cubic centimeters. The white blood cell count remained elevated around 18,000 until the twelfth day. The temperature gradually fell from 104 F, then rose to 103 F again and subsequently dropped to normal. He was discharged on the twenty-seventh day as fully recovered.

CASE 10—S H, a Negro aged 71, entered the hospital complaining only of a sore knee of one week's duration. On admission a diagnostic tap revealed 60 cc of purulent fluid containing pneumococcus type VII, 50 cc of purulent fluid aspirated on the seventh day was again positive. In eight days he received a total of 9 Gm of sulfadiazine and later 26 Gm of sulfathiazole with drug levels as high as 9.1 mg per hundred cubic centimeters. The temperature was 100 F on admission, rose to 102 F and gradually fell to normal in fourteen days. The white blood count rose to 17,100 at the time of the temperature spike. He left the hospital on his eighteenth day with some limitation in flexion.

CASE 11—E B, a Negro woman aged 39 entered the hospital with pneumonia of the right lower lobe and bacteremia due to pneumococcus type VIII. Subsequent blood cultures were sterile but a diagnostic aspiration of 1 cc of gelatinous material from the ankle on the second hospital day revealed pneumococcus type VIII. The joint fluid was again positive on the eighth day when 6 cc was removed, but became sterile, as shown by subsequent taps—one of 30 cc or serous bloody fluid, another of 4 cc of bloody watery fluid. In twenty-one days she received a total of 58 Gm of sulfathiazole followed by 60 Gm of sulfadiazine. Sulfadiazine was substituted because of apparent sulfathiazole intoxication. On the fifth day she received 75,000 on the seventh 100,000 and on the ninth 80,000 units of specific serum a total of 255,000 units because she was not fever free and joint cultures were still positive. With this treatment and with blood levels over 4 mg per hundred cubic centimeters her white blood cell count dropped from 41,000 to 10,300 and her joint became better. She signed out of the hospital as fully recovered or her joint difficulty but with her pneumonia still not completely resolved. She was seen a month later and was entirely well.

SUMMARY

The 11 cases of pneumococcal pyarthrosis presented show the results of conservative specific treatment.

Three patients died, 2 receiving no specific treatment and the third receiving serum in insufficient amounts. Eight patients recovered completely.

With specific sulfonamide or serum treatment, repeated aspiration is recommended. Surgical drainage was found unnecessary.

Emotional Thinking—At the basis of most immature attitudes will be found emotional thinking, which consists primarily of jumping to conclusions because of the undue influence of wishes or fears, or because of lack of training in the proper way of thinking.

Emotion is an integral part of the bodily process and the expression of the basic drives and energy of the organism.

Just as emotion without the direct control of the intellect degenerates into blind excess, so the intellect without the driving force of emotion remains sterile, incapable of accomplishment.

Logical thought or reason is direct clear influenced only by facts and based on premises arrived at objectively and understandingly.—Kranz, Samuel H. *The Therapy of the Neuroses and Psychoses*. Philadelphia: Lea & Febiger, 1943.

Clinical Notes, Suggestions and New Instruments

MONOCULAR MYASTHENIA GRAVIS

SIGMUND S. WINTON, PH.D., M.D., CHICAGO

A recent report by Moore¹ has directed attention to the fact that occasional cases of myasthenia gravis exhibit no symptoms or signs other than those referable to the ocular apparatus. Coincidentally, he raises considerable speculation as to the frequency with which this monosymptomatic form of myasthenia is erroneously diagnosed as neurosyphilis, organic oculomotor palsy or some similar neurologic condition. Although ocular signs and symptoms are numbered among the common clinical features of myasthenia, their correct etiologic basis is often overlooked until other unmistakable and more widespread concomitants have made their appearance. Two cases illustrative of this condition, i.e. monocular myasthenia gravis, are described. In 1 of these neurosyphilis had been suspected as the etiologic factor. In the other, in which diplopia was complained of, the clinical picture, in addition to ptosis, suggested the diagnosis of oculomotor nerve paralysis. Moore also cites 1 case seen several years earlier in conjunction with Winkelmann.² Diagnosis of neurosyphilis and a post-traumatic state had been made and both antisyphilitic treatment and operative procedures were carried out before the correct nature of the condition was brought to light. These instances further serve to illustrate the difficulties of accurate diagnosis by observation alone. Electromyographic and electroergographic methods and other tests such as the Jolly reaction can be used to ascertain the state of skeletal muscle function. However, as Moore points out, all these methods are either unsuitable for testing ptosis or require cumbersome or elaborate apparatus. Under such circumstances, practicability dictates the use of a simpler and more reliable test. That prostigmine is valuable as a diagnostic agent as well as in treatment is illustrated in the case reported here.

Fig. 1—Appearance of patient before treatment with prostigmine methylsulfate

REPORT OF CASE

History—M. T., a girl aged 16 years, complained of drooping of the left upper eyelid of sudden onset. She stated that three weeks prior to this event she had been suffering from a moderately severe head and chest cold, which cleared up with

Hoffmann-La Roche, Inc., made generous contributions of prostigmine in the treatment of this case.
¹ Moore, M. T. Monocular Myasthenia Gravis. *Prostigmine Methylsulfate as a Differential Diagnostic Agent*, Arch. Ophth. 26: 619 (Oct.) 1941.
² Winkelmann, N. W., and Moore, M. T. *Prostigmine in the Treatment of Myasthenia Gravis and Muscular Dystrophy*, Arch. Neurol. & Psychiat. 37: 237 (Feb.) 1937.

medication and rest. For about ten days she had felt her usual self, then one morning awoke to find the upper left eyelid drooping and almost covering the pupil. She experienced no unusual general fatigue but noticed that she was unable to raise the eyelid even on extreme effort. On the advice of a physician she applied hot fomentations to the left side of the face and continued this treatment for about two weeks without

Fig. 2—Same patient one month later while under treatment with prostigmine methylsulfate

any sign of improvement. The patient had no difficulty in chewing her food, in swallowing or in phonation, nor was there any history of hysteria, temperamentality or emotional upset. Her appetite was good and her diet well balanced. Her weight, which had varied little in the past year, was 103 pounds (47 Kg). She did not complain of discomfort in her neck or chest or of chronic cough or sputum. Exercise caused no unusual fatigue of the muscles of the extremities.

Physical Examination—On examination two weeks after the onset of this condition, the patient appeared well nourished and well developed. There was a pronounced ptosis of the left upper eyelid, which could not be raised even with the utmost effort (fig. 1). The lower border of the lid crossed the center of the pupil. There were no ophthalmoplegia and no impairment of visual acuity. The pupils were round and equal on both sides and reacted to light and in accommodation. There was no abnormal facial expression, she was able to laugh, frown and wrinkle her forehead with ease. The gag reflex was present and there was no evidence of impairment of either chewing or swallowing. There was no cervical adenopathy nor any evidence of thymic enlargement. The chest was well developed and the heart and lungs were normal. The abdomen was scaphoid in contour. Careful examination of the extremities revealed no superficial abnormalities, atrophy, hypertrophy or fibrillary twitchings. The power of the muscles was good and the deep reflexes active and equal on the two sides.

Laboratory Examination—Hemoglobin was 90 per cent, red blood cells numbered 5,000,000 and white blood cells 7,300 with lymphocytes 40 per cent, polymorphonuclears 59 per cent, eosinophils 1 per cent and basophils 0. Urinalysis showed absence of albumin and sugar. Microscopic examination was negative. The blood Wassermann reaction also was negative. Ergographic tests were omitted as there was no evidence of general muscular weakness. When 1 cc of prostigmine methylsulfate (1:2,000) was injected subcutaneously as a therapeutic test a definite response was obtained within fifteen minutes. The eyelid began to fibrillate slightly and then gradually began to rise until the lower border reached the upper edge of the pupil.

Treatment—At the beginning of treatment the patient was given one injection of prostigmine methylsulfate 1:2,000 twice weekly. Following each injection the ptosis disappeared and

the eyelid regained its normal tone and power (fig 2), which effects lasted for only a few hours. In order to increase the concentration of prostigmine in the blood prostigmine bromide tablets were given in 15 mg doses three times daily in addition to the weekly hypodermic injection. The lid remained constantly elevated and had good tone and power but occasionally fibrillated and appeared overcompensated. When the total daily dose of the bromide was dissolved in water and taken in smaller but more frequent quantities throughout the day fibrillation was less often seen. On several occasions the patient complained of headaches and abdominal cramps. After several months on this management the patient developed a tolerance to prostigmine and at various occasions noticed slight drooping of the lid. Guandine hydrochloride in the dose of 0.1 Gm three times daily was then substituted for prostigmine but the results were not satisfactory. Ephedrine sulfate and potassium chloride also failed to produce any improvement in the ptosis. The best results were obtained with a combination of 15 mg of prostigmine bromide and 0.1 Gm of guandine hydrochloride taken three times daily with meals. Under this regimen the patient remained comfortable, active and free from ptosis. After four months the guandine was omitted and the dose of prostigmine gradually reduced, until the patient was taking one tablet (15 mg) every third day. Her condition appeared to progress favorably for about one month, after which the lid gradually began to show signs of weakness and slight ptosis. After combined therapy with prostigmine and guandine was reinstituted however all symptoms remained in abeyance. For the past eighteen months she has been enjoying excellent health.

COMMENT

This case affords an illuminating example of strict localization of myasthenic signs. Whether or not lacking specific therapy, more widespread involvement would have occurred is problematic. A review of the literature shows, however, that ocular abnormalities are often but the forerunners of the full fledged disease. The implications with respect to early diagnosis and treatment seem obvious.

The use of prostigmine for diagnostic purposes has been extensively studied by Viets, Schwab and Mitchell.³ The test consists simply in the intramuscular injection of 15 mg of prostigmine methylsulfate (plus $\frac{1}{100}$ gram [0.00065 Gm] of atropine sulfate) and the observation of the objective and subjective improvement at ten minute intervals for one hour. No apparatus is needed other than an ordinary hypodermic needle and syringe. The treatment of myasthenia by prostigmine methylsulfate and prostigmine bromide is a topic too well known to justify discussion here.

AN IMPROVEMENT IN CATHETER TECHNIC FOR CONTINUOUS CAUDAL ANESTHESIA

FRANCIS R. IRVING, M.D., SYRACUSE, N. Y.

Recently Adams and Lundy¹ described the catheter technic for continuous caudal anesthesia. The method they described involved the use of a 13 gage Love-Barker spinal needle and a number 5 ureteral catheter. We² have used this method in over 250 obstetric cases without any serious complications. There are, however, some objections. 1 The caliber of the needle is such that it is difficult to insert it into the caudal canal. 2 If there is difficulty in locating the caudal foramen and it becomes necessary to reinsert the needle, considerable trauma ensues. As a result patients complain of soreness at the site of insertion during the first few days post partum.

Recently we have overcome this difficulty and simplified the technic considerably by employing a 15 gage needle with obtu-

rator and a number 4 ureteral catheter. It is much easier to insert a small caliber needle into the caudal canal. The 15 gage 3 inch needle is considerably smaller than the 13 gage. This difference in size stands out when the needles are placed side by side.

For obese persons or for patients with a small sacral foramen we use a special 18 gage needle $5\frac{1}{2}$ inches long. This needle is hubless and was devised through the cooperation of Mr. Oscar Schwidetzky, manager of the research department of Becton Dickinson & Co. We employ this needle in the difficult cases. After it is inserted, the 15 gage needle without the obturator is passed over it as a sleeve. The 18 gage needle is then removed. The number 4 ureteral catheter is inserted into the caudal canal through the 15 gage needle, which is withdrawn leaving the catheter in place. A 25 gage hypodermic needle is inserted into the external end of the catheter which is connected by an adaptor to an injection system similar to that described by Hingson and Edwards. The 15 gage needle can be used direct in over 75 per cent of cases; the hubless 18 gage needle being reserved for the difficult patient. We have employed this method in over 100 cases. It is notable that there are less complaints from patients with regard to soreness and irritation at the site of puncture.

The use of a number 4 ureteral catheter was reported by Manalan³ but he employed a 14 gage needle.

The catheter method obviates the danger of a broken needle, which can be a major complication.⁴ Patients can move about freely and are more comfortable. We believe it will be the method of choice in obstetric cases in which continuous caudal anesthesia is employed.

The number 4 ureteral catheters can be obtained from the American Cystoscopic Company or the Bard Company, 79 Madison Avenue, New York City. They are boilable and can be used many times.

Special Article

TYPHOID IN THE LARGE CITIES OF THE UNITED STATES IN 1942

THIRTY-FIRST ANNUAL REPORT

A communication was addressed to the health officer of each of the cities, requesting the number of deaths from typhoid, excluding paratyphoid, both among residents and among nonresidents as recorded for 1942. In addition to the tendency for many cities to keep no data on reallocations for residents there was observed a distinct carelessness on the part of some health officials to submit accurate and complete figures. In many instances the number of cases was given and only the challenge of the reviewer brought forth the data requested. For other cities multiple inquiries brought forth irreconcilable replies. Too frequently the answer was left to a subordinate employee, although there is evidence that in the largest cities the health officer has established a routine whereby he gives final approval to statistical data released by his department. It is recommended that the smaller cities follow this excellent example. A few health officers seem to have no knowledge of how many typhoid deaths have occurred in their community and this information can be secured

Incomplete data.

estimates using ration book data or adjustments which are questionable. Except for Washington, the Bureau of Census has prepared no population estimates for cities since the 1940 census. Registration data for War Ration Book One was reported only on a county basis and similar estimates for cities are not available. Since no official figures are available for any date subsequent to that of the federal census, it has again been deemed advisable to employ the populations determined by this uniform tabulation. It is recognized that in areas of concentration of military and industrial activities a slight error will result, and some city and group rates may be a little too high and even too low.

Paratyphoid has again been excluded. Special note has been made of cities in which all deaths occur among nonresidents. In addition to the fifty-three cities enumerated on the honor roll in table 10, ten cities (Birmingham, Dallas, Indianapolis, Jacksonville, Knoxville, Nashville, Pittsburgh, San Diego, St. Louis, Utica) are qualified for such acclaim but have been charged with typhoid deaths among nonresidents cared for in these cities. In nine other cities (Atlanta, Baltimore, Buffalo, Cincinnati, Jersey City, Kansas City, Kan., Louisville, New Orleans, Washington) more than one third of the reported deaths were stated to have

been among nonresidents. One city with more than one million inhabitants (Detroit) records no death from typhoid.

The number of cities with no typhoid death during the past two or more years has increased from twenty-five in 1941 to thirty-one in 1942 (table 9). Fort Wayne continues to head the list with no death in eight years. South Bend has maintained its excellent record and has been without a death for seven years. Fall River, Lynn and New Bedford report no death in six years, Cambridge and Lowell, no death in five years.

The New England cities (table 1) (population 2,579,152) have the lowest group rate (0.12) but are closely followed by the East North Central cities (0.14) and the Middle Atlantic cities (0.15). The West North Central cities (0.18) are not far behind. Eleven of the New England cities (there were eight in 1941, ten in 1940, eleven in 1939) report no death from typhoid in 1942 (table 1). Cambridge, Fall River, Hartford, Lowell, Lynn, New Bedford, Somerville and Springfield have maintained their ranking of 1941, while Bridgeport, New Haven and Worcester have been added to the honor roll. Springfield reports no death

Incomplete data.

among residents during the past nine years, Hartford none for five years. While in 1940 one half of the eighteen cities recording no deaths from typhoid during a two year period were to be found among the New England cities and in 1941 one third (eight among twenty-five) were from these cities, in 1942 one fourth (eight among thirty-one) were from this group. This in no manner subtracts from the outstanding record of the New England cities but rather does it show the

tendency for other cities to attain the high standards set by this group. Worcester, with the first death in 1941 among residents for eleven years, now returns to the honor roll, Bridgeport and New Haven, each with one resident death in 1941, also return to the honor roll. Bridgeport reported no deaths during the

† One third or more of the reported typhoid deaths were stated to be in nonresidents.
‡ Incomplete data.

five year period 1935-1939. Boston reports one death among residents (the same as for 1941). For the fourteen New England cities there were but three deaths, all among residents, one each for Boston, Providence and Waterbury. The rate (0.12) is the lowest thus far attained by any group of cities (table 13). The New England cities regain first place, which position they held during the quinquennium 1936-1940.

Eleven of the large Middle Atlantic cities (there were eight in 1941, nine in 1940) report no death from typhoid in 1942 (table 2). Albany, Erie, Newark, Scranton, Trenton and Yonkers have maintained their ranking of 1941, while Camden, Elizabeth, Paterson, Reading and Rochester have been added to the honor roll. The Middle Atlantic cities have a group rate (0.15) which is but slightly higher than that of the New England and East North Central cities. It is much lower than the rates for 1941 (0.24), 1940 (0.27) and 1939 (0.37). Six cities (Albany, Erie, Newark, Scranton, Trenton, Yonkers) report no typhoid death during 1941 and 1942 (table 9), Yonkers none for four years, Erie, Newark and Scranton none for three years. After the passage of five years with but one death among residents in Buffalo it is stated that in 1942 there occurred three deaths, two among residents. Utica reports only one death among residents during the past eleven years, Erie one such death for eight years. For the first time Pittsburgh records no death among residents (there were three in 1941) and only one among nonresidents (there was but one resident death in 1933 and again in 1939). After a period of six years with no death among residents Syracuse records one such death in 1942. Rochester reports but one death during the past three years. New York records a significant decrease in the number of deaths

(five in 1942, all among residents, fourteen in 1941, thirteen among residents). It is stated that in Philadelphia there occurred seven deaths, all among residents. There were seven deaths in 1941 (five among residents) and twelve in 1940 (eleven among residents). Jersey City reports two deaths, one among residents. In the group as a whole (population 13,129,185) there were twenty deaths in 1942 compared with thirty-one in 1941, thirty-six in 1940 and forty-eight in 1939.

The rate (0.70) for the South Atlantic cities (table 3) (population 2,727,985) is lower than the rate of 1941 (0.88) and that of 1940 (0.73). In these cities there occurred nineteen deaths in 1942, twenty-four in 1941 and twenty in 1940. The number of deaths among residents has decreased from thirteen in 1941 to ten in 1942. Three cities (Charlotte, Norfolk, Wilmington) are on the honor roll, and it is stated that the one death in Jacksonville occurred among nonresidents. Five cities (Atlanta, Baltimore, Richmond, Tampa, Washington) report that one third or more of deaths were among nonresidents (one of three in Atlanta, two of three in Baltimore, two of four in Richmond, two of five in Tampa, one of two in Washington). Charlotte (no death in 1942) has been included in the group for the third time, however, for purposes of adequate comparison the figures for this city have been omitted in calculating rates for the group as a whole.

‡ Incomplete data.

The East North Central cities (population 9,386,378) have lost first place, which rank they held in 1941 and back in 1938. Twelve (eleven exclusive of Gary) of the cities in this group (Akron, Canton, Dayton, Detroit, Evansville, Fort Wayne, Gary, Grand Rapids, Milwaukee, Peoria, South Bend, Youngstown) report no death from typhoid in 1942 (table 4). Gary was added to this group in 1940 but figures for this city have been omitted in determining rates for the group as a whole. The number of typhoid deaths decreased from nineteen

(thirty-three in 1940) to thirteen (the rate from 0.35 in 1940 and 0.20 in 1941 to 0.14). Six cities (Akron, Canton, Evansville, Fort Wayne, Grand Rapids, South Bend) record no typhoid death during 1941 and 1942 (table 9), Fort Wayne none for eight years, South

The six cities (table 5) in the East South Central group (population 1,286,747) again show a continuing decrease in the death rate (0.54 in 1942, 0.70 in 1941, 2.09 in 1940, 2.58 in 1939). Especially impressive is the fact that there was but one death among residents, the total of seven deaths includes six among nonresidents. The effect of hospitalizing cases from surrounding rural areas remains evident. Two cities (Chattanooga and Memphis) report no deaths among either residents or nonresidents and appear on the honor roll. The two deaths each in Birmingham and Knoxville as well as the one death in Nashville were stated to be among nonresidents. The single resident death occurred in Louisville, which city reports two deaths in 1942 (three in 1941, two among residents). Especially noteworthy is the decrease in Memphis from fifty-eight deaths (twenty-seven among residents) during the five year period 1936-1940 (an average of nearly twelve deaths a year) to no death in 1942. Knoxville reports no death among residents during the past two years.

The West North Central cities (population 2,716,484) show a decrease in the number of deaths

1949	93	0	1	3	5	34	30

* Charlotte, Gary and Sacramento omitted

from eight to five, three of the five were among residents. The death rate declined from 0.29 in 1941 (0.41 in 1940) to 0.18 in 1942. Five cities (Des Moines, Duluth, Kansas City, Mo., Minneapolis, Omaha) record no death and St. Louis reports one death among nonresidents. Wichita after no death for five years now reports one among residents, St. Paul also records such a death. Three cities (Des Moines, Duluth, Omaha) report no typhoid death during 1941 and 1942 (table 9), Duluth none for four years, Des Moines none for three years. Kansas City, Kan., records two deaths, one among nonresidents. St. Louis establishes a new record with no death among residents (there were two such deaths in 1941 in addition to two among nonresidents).

The eight cities of the West South Central group (table 7) (population 2,048,692) again report a decided reduction in the death rate (2.00 in 1940, 1.37 in 1941, 0.73 in 1942). The actual number of deaths decreased from twenty-eight (forty-one in 1940) to fifteen. Of the fifteen deaths in this group of cities, six were among nonresidents (seventeen of twenty-eight in 1941). Two cities (Oklahoma City, Tulsa) record no death and Dallas reports one death among nonresidents. Tulsa reports no death for three years. Two cities (El Paso, New Orleans) record one third or more deaths among

nonresidents. Of five deaths in El Paso, two were among nonresidents, three out of four in New Orleans, Houston and San Antonio each report two deaths among residents. Fort Worth one such death. This group of cities continues to have the highest group rate.

TABLE 12—Total Typhoid Rate for Seventy-Eight Cities 1910-1942*

	Population	Typhoid Deaths	Typhoid Death Rate per 100,000

Rates for Ninety-Three Cities

1930	2,700,000	300	1.04
1931	2,700,000	300	0.30
1932	2,700,000	300	0.20
1933	2,700,000	300	0.20
1934	2,700,000	300	0.20
1935	2,700,000	300	0.20
1936	2,700,000	300	0.20
1937	2,700,000	300	0.20
1938	2,700,000	300	0.20
1939	2,700,000	300	0.20
1940	2,700,000	300	0.20
1941	2,700,000	300	0.20
1942	2,700,000	300	0.20

The following fifteen cities are omitted from this table because data for the full period are not available: Canton, Chattanooga, Dallas, Fort Wayne, Jacksonville, Knoxville, Long Beach, Miami, Oklahoma City, South Bend, Tampa, Tulsa, Utica, Wichita, Wilmington.
* Data for Fort Worth lacking.
† 1940 census figures used.

(0.73), but this compares most favorably with the New England rate of ten years ago (0.70 for 1931-1935) and is quite a contrast to the group's own rate for the same quinquennial period (5.36).

TABLE 13—Total Typhoid Death Rate per Hundred Thousand of Population for Ninety-Three Cities According to Geographic Divisions

Population*	Typhoid Deaths		Typhoid Death Rates				
	1942	1941	1942	1941*	1940	1935	1930
New England	2,619,152	3	0.12	0.23	0.39	0.70	1.31
Middle Atlantic	13,129,180	20	0.15	0.24	0.43	0.80	1.40
South Atlantic	2,727,900	19	0.24	0.53	1.14	2.70	4.50
East North Central	9,386,378	13	0.14	0.20	0.33	0.75	1.29†
West North Central	1,286,747	7	0.34	0.70	2.24	4.81	8.31
East South Central	2,716,484	5	0.15	0.29	0.60	1.24	1.83
West South Central	2,048,032	15	0.31	1.37	3.09	5.36	7.30
Mountain & Pacific	4,180,032	13	0.31	0.55	0.60	0.85	1.50

† Data for South Bend for 1935-1939 are not available.
* Lacks data for Oklahoma City in 1930.
* 1940 census figures used.

The eleven cities (excluding Sacramento) in the Mountain and Pacific states (table 8) (population 4,186,039) report a decrease from sixteen deaths in 1941 to thirteen in 1942 (there were but thirteen deaths in 1940). The rate has decreased from 0.38 to 0.31. Sacramento has again been omitted in calculating the total number of deaths and the rates. This city reports

no death. Seven of the Mountain and Pacific cities (Long Beach, Oakland, Portland, Sacramento, Salt Lake City, Seattle, Tacoma) report no death from typhoid in 1942. Long Beach, Oakland, Portland and Seattle have maintained their ranking of 1941. Portland and Seattle report no death during the past three years. It is stated that the one death in San Diego was among nonresidents. Of three deaths in Denver, one was among nonresidents. Los Angeles reports seven deaths, six among residents (there were ten in 1941, six among nonresidents). San Francisco records one death among residents (there were two in 1941, one among residents). With no death in 1940 and 1941, Spokane reports one among residents in 1942.

THE HONOR ROLL

The number of cities with no death from typhoid has increased from thirty-six to fifty. The three cities (Charlotte, Gary, Sacramento) not included in the ninety-three (table 11) also report no death. While this is by far the best showing, there remain four cities with rates of 20 or more. The charge of nonresident deaths accounts in part for these high rates. The number of cities with rates of less than 10 has increased by two (eighty-four in 1942, eighty-two in 1941). Thirty cities (thirty-one with Gary) record no typhoid death in 1941 and 1942 (table 9). There were only twenty-five cities a year ago that reported no death for a period of two years or longer. It is again emphasized that several other cities in the first rank would appear in the honor roll were they not charged with deaths among nonresidents.

For the seventy-eight cities (table 12) for which data are available since 1910 there occurred eighty-three deaths from typhoid, which is by far (less than one half that of 1940) the lowest of record. Deaths were recorded at the rate of 0.23 per hundred thousand of population. For the ninety-three cities the number of deaths in 1942 is ninety-five (141 in 1941). The rate has decreased from 0.50 in 1940 to 0.37 in 1941 and to 0.25 in 1942 (a 50 per cent reduction in two years). Of the ninety-five deaths in the ninety-three cities, thirty-two deaths (one third) were among nonresidents. The health officers report no special outbreaks of typhoid. Improvement has been general throughout the country but especially in the West South Central cities, where the highest rates have been reported during the past many years. War travel does not appear to have contributed to the typhoid problem in our large cities.

PROBLEMS OF INFECTIOUS JAUNDICE

A full understanding of the disease or diseases called infectious or epidemic jaundice or hepatitis has not been reached, as the confusion of the nomenclature bears witness. Whether "catarrhal jaundice" in the old sense of jaundice ascribed by Virchow in 1864 and others before him¹ to closure of the common duct in the course of a duodenal "catarrh" occurs as a distinct disease is still questionable. Does the term possibly cover two morbid conditions, one due to biliary obstruction and the other to hepatic changes without obstruction? The present general view is indicated by the increasing use, particularly by European writers, of the term "infective or epidemic hepatitis." The nature of the hepatitis and of other changes has not been exhaustively studied, the mechanism of the jaundice has not yet been explained, and the cause or causes are not known, significant progress is being made, however, in the study of these problems.

By aspiration biopsy of the liver in 26 cases of sporadic jaundice of the catarrhal type Roholm and Iversen² confirmed previous reports of diffuse changes in the liver in such cases. A cannula was inserted in the posterior axillary line of the ninth right interspace through which were aspirated, by means of a record syringe, columns of liver tissue 1 to 2 cm long and 2 mm in diameter. The procedure was employed in various stages of the disease, but mainly one week or so after the appearance of jaundice and three or four weeks later. The liver presented a general disarrangement of its cells with necrobiotic changes, infiltration with mononuclear cells and increase of connective tissue in the portal spaces around the central veins and also in the lobules. Although pronounced in the first week, the changes subsided within a month after the appearance of the jaundice. The interlobular biliary ducts were normal. The jaundice may have been due to

failure of the biliary pigment to reach the ducts on account of the changes in the liver cells. The occurrence of fatal subacute atrophy of the liver in one of the cases suggests again that fundamentally acute yellow atrophy may be of the same nature as the acute diffuse hepatitis. Findlay and Dunlop³ found that in the literature "the association between epidemic catarrhal jaundice and acute necrosis of the liver has been extremely striking." The Danish investigators conclude that the diffuse hepatitis probably is hematogenous. Similar studies should be made in the course of epidemics of infectious jaundice and of jaundice following the injection of human plasma or serum.

Clinically this type of jaundice clearly concerns an infectious disease or diseases naturally communicable, mainly, so it seems, by contact, and produced artificially by the injection of human serum or plasma containing infectious icterogenic agents the exact nature of which is as yet unknown. Research may determine whether what is now termed infectious jaundice or hepatitis is a single disease and also settle the question whether the spontaneous and the artificial forms are identical. On request of the Ministry of Health, the Medical Research Council⁴ in England has undertaken a comprehensive investigation of the incidence, causes and diagnosis of different forms of jaundice. This investigation is in competent hands, and valuable results will no doubt be forthcoming. Significant too is the growing concern about infectious jaundice, as shown by the fact that it has been made recently a reportable disease in Illinois and perhaps also in other states.

There are no specific diagnostic tests for infectious jaundice. In doubtful cases of fever with jaundice, leptospirosis (Weil's disease) or even yellow fever might be suspected. In leptospirosis the serum of the patient usually agglutinates *Leptospira icterohemorrhagica*, and the urine may transmit the infection to guinea pigs. In yellow fever microscopic examination of the liver will yield information of diagnostic value, and in recovered patients not previously inoculated against yellow fever search for protective bodies against the fever in the blood may be of help. In epidemics of infectious jaundice or hepatitis it is believed that the disease may be spread at least to some extent by patients whose symptoms suggest the disease but in whom jaundice does not appear. In such cases examination of the urine and the blood for biliary products may be of value.

Advances in the diagnostic, experimental and other aspects of infectious jaundice await the determination of its cause. In a previous editorial⁵ reference was made to the transmission of the disease to volunteers.

by nasal washings in salt solution from patients with jaundice following the injection of yellow fever vaccine, and by the oral ingestion of duodenal washings as well as the injection of serum and blood from patients with spontaneous jaundice. Animal experiments with such materials do not seem thus far to have yielded any conclusively positive results. The failure to find any bacterial cause for infectious jaundice strengthens the suspicion current for some time that it may be a virus disease or diseases. A report⁶ has come to the effect that a virus has been cultivated from the duodenal fluid of patients with 'hepatitis epidemica' on the developing hen's egg. Further reports on work along this and other lines will be awaited with special interest.

HOUSING AND HEALTH

The exact effects of substandard housing on the health of the inhabitants are difficult to estimate, generally it is accepted that illness may be directly fostered by bad housing conditions. The concept of bad housing includes overcrowding, overcrowding alone facilitates the spread of certain infectious diseases particularly tuberculosis, other contagious diseases of the respiratory system, and such diseases as diphtheria, scarlet fever and meningitis. Insanitary dwellings are usually overrun with rats, which also spread some diseases such as typhus. Insanitary conditions for disposal of excreta and improper central water supply food and milk are more frequent in both urban and rural substandard housing areas. Typhoid and the dysenteries flourish in these regions. In some places mosquito breeding pools and unscreened dwellings are conducive to excessive malaria among the residents. The venereal diseases also are excessive in substandard and overcrowded housing regions. Diseases due to deficient vitamins or food and lack of sunshine are similarly frequent out of all proportion in areas where housing is deficient. The effect on the mental and emotional health of these residents, although more difficult to determine, must be considerable.

Improvement in housing is usually opposed by those who fear an adverse financial effect by removal of rental income and those who hesitate because of the cost. The medical profession is deeply interested in this as in all other factors which influence the health of the people. The elimination of bad housing along lines of sound practice together with the institution of suitable safeguards against the mere transfer of people from one area of bad housing to another is a program which the medical profession can urge as a contribution to the health of the community.

Such programs may be expected to improve the health records and general well being of the communities in which these steps can be taken. Good housing is not

however, a panacea for disease. Solution of the problem of substandard housing for example, could not be expected to eradicate disease, it could not be expected to eliminate ignorance or poverty. It would not solve the problem of the supply and demand for medical care among the poor, it would not insure high standards of medical practice, nor would it furnish any guaranty that those removed from the slums—whether urban or rural—would become at once self-respecting, cleanly, hard working or economically successful citizens.

One of the most pressing health problems facing this country immediately after the end of the war will be the elimination of substandard housing conditions and the building of new facilities. The programs adopted to accomplish this end should be in process of planning now. In considering a housing program one must take into account its place in the general economic situation. If the cost of housing forces deficient nutrition, the housing may well be postponed. If transportation from a new housing area increases loss of time or absenteeism in work, it may not be a desirable benefit. If a housing project leads to racial warfare the result is not wholly a social gain. These considerations indicate again how many factors are involved in every move toward improved security and the necessity for taking every possibility into account in making final decisions.

BIOLOGIC PECULIARITIES OF INTRACRANIAL NEOPLASMS

Most intracranial tumors are characterized by several interesting biologic differences from tumors elsewhere in the body. Regardless of their rate of growth, degree of aggressiveness ability to infiltrate and other characteristics usually associated with cancers, they do not metastasize to distant parts of the body. Cancers which arise elsewhere can metastasize freely into the central nervous system indicating that the incompatibility of protoplasms is not absolute. When intracranial tumors metastasize they do so by implantation.

Using medulloblastomas as an example, Abbott and Kernohan¹ recently considered some additional special problems in the behavior of these tumors. They accept the statements that tumor cells are often free in the cerebrospinal fluid and that they spread by circulation of the fluid and by gravity. Such free cells from medulloblastoma, they point out, frequently become implanted, whereas in other tumors which are equally cellular they usually fail to grow. Thus this system appears to be unequally susceptible to the growth of neoplastic cells arising from the same system. Perhaps this problem is related to the general biologic problem of selective susceptibility and resistance of certain tissues to tumor growth such as is illustrated by the

1 Abbott, Kenneth H. and Kernohan, James W. Metastases Concerning the Problems of Spinal Metastases and Meningeal Metastases of Six Cases and Discussion of the Problems Involved. *Bull. Los Angeles Neurol. Soc.* 5:1 (March) 1943.

6 Siede and Luz. *Klin. Wchnschr.*, Jan. 23, 1943, quoted in *Bull. Ill.* 18:361 (May) 1943.

susceptibility of the spleen to the growth of malignant melanoma cells and its resistance to most other neoplastic cells

The origin of medulloblastoma is believed to be from persistent fetal cells. Most of these tumors are found in childhood, but the time of beginning of their growth remains uncertain because the duration of the clinical course after the onset of symptoms shows wide variation. The implantation metastases may grow to large size and yet produce few symptoms. The authors consider the possibility that the multiple growths do not represent metastases but instead tumors of independent origin. As an explanation for the differences in behavior they suggest that the neoplasms now classified as medulloblastoma might really be several different kinds of tumors.

To the old unsolved problem of the failure to form distant metastases are added those of varying ability to metastasize locally by implantation, of multiple tumors versus metastases, of causes for the differences in rate of growth, and of the failure of many tumors to produce symptoms. Some of these problems may be solved by careful studies of the natural history of the tumors. For others fundamental chemical studies may be necessary.

Current Comment

SEMINAL FIBRINOLYSIN

Discovery of a proteolytic enzyme in human semen practically identical with the fibrinolysin secreted by virulent strains of hemolytic streptococci has been reported by Huggins¹ of the Department of Surgery, University of Chicago. Human, guinea pig and canine semens are delivered in a liquid state, after which human and guinea pig semens coagulate to form an elastic solid, while canine semen remains fluid. Coagulated guinea pig semen remains in a solid state in the vagina for several days. Solidified human semen is spontaneously liquefied in a few minutes. Seminal coagulation is believed to be due to fibrinogen and thromboplastin² derived from a special region of the prostate³. Liquefaction of the resulting coagulum is apparently due to the combined action of two enzymes, a fibrinolysin and a "fibrinogenase." "Fibrinogenase" is dominant in canine semen, thus preventing coagulation, while fibrinolysin is dominant in human semen, lysis taking place only after the formation of the seminal clot. This fibrinolysin is present in full titer in normal human prostatic secretion but is absent from hydrocele and spermatocele fluids and from all other human body fluids thus far tested. Many points of similarity occur between the human prostatic fibrinolysin and the streptofibrinolysin of Tillett and Garner⁴. Both liquefy normal human

blood or plasma clot but are inactive against rabbit clots. Under certain pathologic conditions human blood becomes immune to streptolysin, presumably because of the presence of a specific antistreptococcus antibody. The same antibody neutralizes human seminal fibrinolysin. A theory is not as yet suggested as to the purposeful function of the newly discovered fibrin liquefying prostatic factor, which may well prove to be of practical clinical interest.

COURSE IN HEALTH EDUCATION

On page 1194 in this issue of THE JOURNAL appears an announcement of the lecture-observation-demonstration course in the health education and related work of the American Medical Association recently given to twenty-nine graduate students in health education studying under fellowships granted by the W. K. Kellogg Foundation and supervised by the United States Public Health Service. The visit of these students to the American Medical Association was arranged under authorization by the Board of Trustees¹ permitting the Bureau of Health Education to arrange such opportunities for qualified students. At the end of the week's work, officers of the United States Public Health Service who accompanied the group and members of the group expressed amazement at the scope and character of the work of the several departments of the American Medical Association, of which they had previously had only the vaguest idea. It was the consensus of the group and of the headquarters staff who participated in the demonstrations that the benefits of such a visit are mutual. The students learn much about the medical profession, and the medical profession in turn will benefit by better understanding and cooperation on the part of these students when they make their contacts with physicians in their life work as health educators attached to local (city and county) health departments.

DRUGS AND ESSENTIAL HYPERTENSION

THE JOURNAL¹ recently commented on the extreme fluctuations of the blood pressure which may occur without drug intervention. J. S. Kapernick² has reported a study of several drugs which permitted him to conclude that these drugs, "when administered continuously in optimal dosage for periods of four weeks, do not possess any significant hypotensive effect on the blood pressure of hypertensive patients." The agents used in the study were those which are in current use and which are claimed to be of value in the management of essential hypertension. The study was thorough and the results are of practical clinical value. The value is emphasized in a discussion of the presentation by E. A. Hines, who stated in part: "In a review of the many articles in the medical literature concerned with the treatment of hypertension it will be observed that

⁴ Tillett, W. S., and Garner, R. L. J. Exper. Med. 58:485 (Oct.) 1933.

in general the results obtained are in inverse proportion to the care with which the study was carried out, in other words, the more adequately controlled the study, the less likely are the results to have been favorable. It is not probable that the false conclusions which were drawn from these studies were the result of wilful misrepresentation or misinterpretation or even of wishful thinking. What then accounts for such a state of affairs? Essentially the confusion is due to attempts to devise a cure without adequately studying the fundamental nature of the disease. More specifically, the false conclusions are due to two things which Dr. Kapernek has largely avoided in this study: (1) the tendency to consider symptomatic relief as the chief criterion or the effectiveness of a drug in the treatment of hypertension and (2) the failure to recognize the importance of the inherent variability of the blood pressure in estimating the effects of various drugs on the blood pressure. This is not to say that symptomatic relief is not desirable in treating hypertensive disease, but it has become apparent that the symptoms associated with hypertension are seldom directly related to the actual height of the blood pressure nor is symptomatic relief necessarily related to survival.

COLLATERAL IMMUNITY IN TUBERCULOSIS

Experimental evidence in support of the belief that an active tuberculous nodule is associated with an increased resistance to numerous other infectious diseases has been recently reported by Ascoli¹ of Middlesex Veterinary School, Waltham, Mass. Twelve years ago it was demonstrated by Bareggi² and other Italian investigators that calves previously vaccinated subcutaneously (not intravenously) with BCG recovered from Pasteurella vituliseptica infections which proved fatal to nonvaccinated control calves and that guinea pigs with subcutaneous tuberculous nodules are insusceptible to experimental foot and mouth disease³ and to Brucella abortus infections⁴. Extirpation of the tuberculous nodules in these guinea pigs was followed by a loss of the nonspecific acquired resistance. Transplantation of the extirpated nodule into normal guinea pigs increased their collateral nonspecific resistance immediately without the delay which occurs following routine methods of vaccination. The role of a local tuberculous nodule to increase nonspecific resistance has been amply confirmed on calves¹. Thus far no acceptable theory has been proposed to account for this collateral panimmunity. It is conceivable that the local tuberculous nodule gives off nonspecific hormones or other growth promoting chemical products, which activate or stimulate nonspecific cytologic defenses in other

parts of the body. According to Brown and Pearce⁵ a similar "anachoretic" panimmunity is caused by a local syphilitic lesion. Ascoli believes that the "anachoretic" phenomenon is also shown by numerous other local proliferative or inflammatory tissues. If so, his "anachoretic" collateral panimmunity would be of wide clinical application.

MARKLE FOUNDATION SUPPORTS STUDY IN TROPICAL MEDICINE

The usual activities of the John and Mary R. Markle Foundation consist of grants in aid of specific research projects in the field of medical sciences. This policy has remained unchanged by the war. The foundation in 1942 was particularly helpful to work in tropical medicine¹. The first grant in this field was an appropriation of \$40,000 to the National Research Council to establish a number of lectureships in tropical medicine in medical schools. The foundation also appropriated \$25,000 to the Association of American Medical Colleges to finance the emergency training of teachers of tropical medicine. Under this arrangement each medical school in the United States and Canada which did not have on its staff at least two men qualified to teach tropical medicine was invited to send a member of its teaching staff for a two months course in tropical medicine at the Army Medical School in Washington and another member of its staff to the Department of Tropical Medicine at Tulane University for a similar course. Aid has also been given to collecting laboratory specimens and slide materials to assist in the teaching of tropical medicine in medical schools. Other grants of the foundation in 1942 covered a wide range of medical subjects including the fields of infections and immunity, ophthalmology, nutrition, chemotherapy, pharmacology, anatomy and physiology, neurology and psychiatry, biochemistry and blood and the cardiovascular system.

THE POLIOMYELITIS SITUATION

The incidence of poliomyelitis in some parts of the United States has reached almost epidemic proportions. Indications are that this will be the worst year for this disease since 1940, when 9,770 cases were recorded. Through August 7 nearly 3,000 cases have been reported, or more than twice as many as appeared during the similar period last year. Elsewhere (p. 1198) appears a tabulation of the latest available figures of reported cases for the areas where this disease is particularly excessive. California, Texas, Oklahoma and Connecticut appear to be the states that are the most seriously affected. Most other parts of the country are relatively unaffected, with no more cases of poliomyelitis than would be expected at this time of year.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

THE COMMISSIONING OF INTERNS AND RESIDENTS

The Officer Procurement Service, Washington, D. C., issued a memorandum (FT-108) on August 7 to commanding generals of service commands, explaining the action to be taken in procuring physician interns and residents for appointment in the Medical Corps of the Army and requiring immediate action by each district office. The physicians to whom this memorandum applies are (1) interns graduated from medical schools during March-June 1943 who have not yet been commissioned in the Army and Navy and (2) residents who graduated in June 1942 or before who have not yet been commissioned in the Army and Navy. All such interns and residents are eligible for commissioning except those previously physically disqualified by the Surgeon General or otherwise ineligible for commissions under army regulations. Interns and residents qualified by Selective Service as IV-F because of physical disability and female interns and residents are potential candidates.

The source of such candidates for medical commissions are the public and private hospitals with 50 or more beds. Immediate contact with the superintendent of all such hospitals must be made requesting the names of all potential intern and resident candidates and permission to get in touch with them at times convenient to all.

District offices will use every effort to sell potential candidates on their patriotic duty to take steps to qualify for commissions. Deferment from induction will not be available to potential candidates on completion of their current internships and residencies. No such candidate who is commissioned will be called to active duty until the completion of his internship or residency. The Army has no intention to deprive hospitals of the services of necessary physicians, interns and residents until completion of their internships and residencies; it has every intention, the memorandum states, to commission in the Medical Corps all such interns and residents at the earliest possible moment, postponing their call to active duty until the completion of their respective terms of their internships and residencies. A list of the names of all potential candidates in these groups who refuse or wilfully neglect to be processed for commission will be maintained.

All potential candidates covered by this memorandum are deemed to be "cleared" by the Procurement and Assignment Service and to have been "determined as available," in accordance with a letter from the Procurement and Assignment Service dated August 7 addressed to all superintendents of hospitals having interns and residents and to corps area and state chairmen. On the same day on which the interns and residents fill out their applications, the hospitals which these physicians are serving should apply to the state chairman of the Procurement and Assignment Service for their deferment until the terms of their internships and residencies have expired. All interns are deferred for the term of one year internship, but if a resident is deemed by the Procurement and Assignment Service as not essential to the hospital he should accept a commission and expect to go on active duty immediately.

THE NAVY WANTS SIX HUNDRED WOMEN DOCTORS

Reserve commissions in the Medical Corps of the Navy are now open to qualified women physicians in the ranks of lieutenant commander, lieutenant and lieutenant (junior grade). The Bureau of Medicine and Surgery has announced an initial request for six hundred women doctors, two hundred of them to be commissioned in each of the available ranks.

Under the terms of Public Law 38, passed by Congress last spring, women doctors are being accepted in the Medical Corps with the same status as men doctors. They will be assigned to duty at various types of shore medical establishments within the continental limits of the United States.

In applying for commissions in the Medical Corps, women doctors must meet the same professional requirements as men and must be approved for military duty by the Procurement and Assignment Service for Physicians in order to prevent undue depletion of medical services in civilian communities. The policy has also been established that women doctors will not be accepted if they are married to Navy men or if they have children under 18 years of age.

The general requirements for women physicians are these: For general medical officers the age limits are 21 to 35, for specialist medical officers the age limits are 27 to 50. Applicants must be graduates of an accredited medical school and have had at least one year's internship in an approved hospital. They must be duly licensed to practice medicine and be a member of a state or local medical society.

An exception to these requirements is made for women who apply for commissions as general medical officers immediately on completion of medical school. In this case the internship, license and membership stipulations may be waived.

In addition, applicants for specialist commissions must have had at least three years' recent practical experience in a particular specialty.

The eight women doctors at present holding commissions as lieutenants (junior grade) with the W-V(S) classification of the Women's Reserve, U. S. Naval Reserve, are eligible for transfer to the Medical Corps with an MC-V(S) or MC-V(G) classification.

Applications should be submitted to the nearest office of Naval Officer Procurement.

APPOINTMENT OF OFFICERS FROM CIVIL LIFE

The Acting Secretary of War, Robert P. Patterson, on July 13 issued a memorandum to the Secretary of War's Personnel Board, Officer Procurement Service, commanding generals of the Army Ground Forces, the Army Service Forces and the Army Air Forces, and Divisions of War Department General Staff, pointing out that, during the period of very rapid expansion of the Army last year and of the critical shortage of commissioned officers, civilians were appointed in larger numbers to commissioned grades. Now the Army is rapidly approaching

its maximum planned strength and officer shortages, except in certain very critical categories, namely officers of the medical department, service pilots and chaplains, have been largely overcome. The Acting Secretary of War, therefore, directed that hereafter the Secretary of War's Personnel Board closely scrutinize all recommendations for appointment of civilians other than the exceptions noted and withhold approval in all cases in which it is not clearly indicated that the individual concerned possesses outstanding special qualifications of a technical or professional nature urgently required by the army and not obtainable from any other source, also that more effective methods be adopted, under direction of the General Staff to

classify properly and assign personnel now in the service, to the end that requirements for commissioned officers with professional or technical qualifications other than those indicated be obtained through the reassignment or qualified officers or through the selection and appointment of qualified enlisted men, that the Assistant Chief of Staff take action to reduce to the minimum the number of special categories that may be appointed from civil life and that the commanding generals of the three major commands and their subordinates refrain from requesting the appointment of civilians as commissioned officers except in cases in which the need is so urgent and the qualifications of the individual so unusual that no other solution is possible

ARMY

HOSPITALIZATION IN THE FINAL BATTLE IN TUNISIA

Lieut. Gen Omar Bradley, commander of the U S Army Second Corps in the final battle in Tunisia, in his report to Gen. George C Marshall, chief of staff covering operations between April 23 and May 9, made the following comments concerning hospitalization

'The medical plan was drawn up so as to provide quick evacuation. Initial locations placed the evacuation hospitals within sound of artillery fire and almost within sight of some of the enemy's bombing operations. Locating these units well forward, however, in no way affected the efficiency of the doctors and nurses, who displayed an admirable coolness and accomplished results which, under normal hospital conditions, would have been considered excellent. Their forward locations reduced the time interval necessary for a wounded man to receive adequate care

The ambulance hauls to the base hospital at Bone varied from 85 to 110 miles over rough and tortuous roads. This distance was too great for evacuation of seriously wounded patients, particularly chest and abdominal cases. As a result the evacuation hospital which had initially been set up to take care of patients who would remain in the area until they could return to duty was given the mission of attending to the more seriously wounded

'When the enemy surrendered in northern Tunisia he was operating a total of five hospitals a total of 600 beds. By May 12 there were 745 enemy patients in our hospitals

'Blood donors in the hospitals became a problem and additional personnel from depot companies and clearing companies or medical battalions were utilized for this purpose. One hospital unit formed its own blood bank by cross matching these individuals, withdrawing the blood and placing it in refrigerators where it was easily accessible. It was found that this blood could be kept for several days and then given cold"

SITES FOR MORE ARMY HOSPITALS

Brig Gen Joseph B Sweet, commanding general of the Communications Zone is reported to have announced that a site has been selected near Beaumont, Calif., for an army hospital of about 750 beds, which it is expected will be completed in October. According to the Banning Calif. Record of July 22 another army hospital of 1000 beds is to be constructed at the city limits of Banning. An evacuation hospital has already been established on this site to take care of soldiers from the desert area

PRISONERS OF THE JAPANESE

According to the Pratt Kan, Tribune of May 21 Capt William E Wilson of the U S Army Medical Corps is being held prisoner of the Japanese in the Philippine Islands. Captain Wilson graduated from the University of Colorado School of Medicine in 1928 and entered military service on Dec 12 1940

Dr Nelson Kauffman formerly of Indianapolis and recently with the thirty-first infantry of the U S Army which was stationed in the Philippines, is reported to be a prisoner of the Japanese in a Yokohama prison camp

CAPTAIN SANDERSON—MEDAL FOR BRAVERY

According to the La Porte, Ind., Herald-Argus of June 17, Capt Richard J Sanderson, formerly practicing physician in Westville and Wanatah, Ind., has been awarded a medal for bravery beyond the call of duty while serving as a flight surgeon with a bomber squadron in New Guinea. Captain Sanderson was assigned to a bomber squadron at Shreveport, La., and later went to Greenville, N C., and Ann Arbor, Mich., in midsummer 1942 the squadron left San Francisco for Hawaii, Australia and New Guinea. Captain Sanderson's heroic deed was recently described as follows in the Chicago Daily News

Somewhere in New Guinea. Today the soldier's medal was awarded to Capt Richard J Sanderson of Westville, Ind. The night after Christmas a B-24, taking off from a darkened runway, cracked up and fell burning in the trees, carrying a full load of 500 pound bombs. As the wreckage burned, with explosion imminent, Sanderson crawled forward to try to save Sgt. Chalmers Yielding of Birmingham, La., who had been thrown out. He reached Yielding and began dragging him back as the wreck exploded. Both escaped, but Yielding later succumbed

Captain Sanderson graduated from the University of Cincinnati College of Medicine in 1936

TWENTIETH CLASS OF MEDICAL ADMINISTRATIVE CORPS OFFICERS

The twentieth class of Medical Administrative Corps Officers at the Officer Candidate School, Camp Berkeley, Texas, graduated on July 21 as second lieutenants. The graduating class comprising two companies, will report to their new stations after ten day leaves and will assume the duties of supply, personnel, training and evacuation in the Army Medical Department. Brig Gen Roy C Heflebower, commandant of the school, delivered the graduating address and presented the new officers their letters of commission and their diplomas. Col George E Armstrong, assistant commandant directed the ceremonies and Major Miles G Bell, executive officer administered the oath of office

BURIAL EXPENSES OF MILITARY PERSONNEL

Headquarters of the Sixth Service Command Chicago issued instructions on August 3 to commanding officers of all camps and posts in that service command calling attention to War Department Circular No 149 dated June 30 which prescribes that burial expenses of military personnel of the United Nations who may die in continental United States are payable from the regular army appropriation. The Sixth Service Command directed that in each case in which expenses of disposition or remains of such personnel are paid a certified copy of the invoice to be used in the substantiation of settlement or a certified copy of the purchase order in lieu of the invoice be furnished.

CONFERENCE ON AVIATION MEDICINE

Rapid studies made by aviation medicine, both in research and in practice, were discussed by the senior surgeons of all commands and the four continental air forces at a three day meeting at Army Air Forces headquarters in Washington, D C. The meeting was called by Brig Gen David N W Grant, Air Surgeon.

Those who attended are, front row, left to right, Col Wood S Woolford, chief of operations, Air Surgeon's Office, Col Charles R Glenn, surgeon, Training Command, Col Robert

Fla, Col Mel Pazdral, surgeon, Southeastern Training Command, Lieut Col Howard A Rusk, professional division, Air Surgeon's Office, Col Wilfred F Hall, surgeon, Miami Training Center, Col Clyde L Brothers, surgeon, Third Air Force, Col E L Gann, chief of personnel section, Air Surgeon's Office, Col Harold H Twitchell, surgeon, Second Air Force, Col Walter S Jensen, executive officer, Air Surgeon's Office, Major Hugh Mullan, Air Service Command, Col Robert M Allott, surgeon, Sioux Falls Army Air Base Station Hospital, Col William F De Witt, surgeon, Station Hospital, Col

Those who attended the conference on aviation medicine

K Simpson, surgeon, Gulf Coast Training Center, Col Cadmus J Baker, surgeon, First Air Force, Brig Gen Eugen G Reinartz, commandant, School of Aviation Medicine, Brigadier General Grant, Col Fabian L Pratt, surgeon, Fourth Air Force, Col Ernest F Harrison, surgeon, Materiel Command, Col Irwin B March, surgeon, Eastern Technical Training Command, Col Duran H Summers, surgeon, Antisubmarine Command, Col Henry C Chennault, chief of profession services, and Col William H Powell Jr, surgeon, Atlantic City, N J.

Those in the back row, left to right, are Col Dan C Ogle, surgeon, Army Air Forces Regional Station, Coral Gables,

Michael G Healy, surgeon, West Coast Flying Training Command, Lieut Col Austin Lowrey Jr, surgeon, Proving Ground Command, Col Otis B Schreuder, surgeon, Air Forces School of Applied Tactics, Col William P Holbrook, chief of professional placement branch, Air Surgeon's Office, Col Gustave E Ledfors, chief of supply, Air Surgeon's Office, Col Ehrling L Bergquits, surgeon, Technical Training Command, Lieut Col Sheldon S Brownton, surgeon, Training Command, Col Paul W Gilliland, surgeon, Air Transport Command, Col Loyd Eugene Griffiths, chief of research division, Air Surgeon's Office.

NAVY

THE WAVES DO EXCELLENT WORK

The Bureau of Medicine and Surgery has received many favorable comments concerning the excellent work being done by the Hospital Corps Waves on duty at naval hospitals throughout the country. Among the 600 selected monthly, more than 10 per cent are qualified technicians in the allied fields of medical work, about 10 per cent are college graduates, and about 25 per cent have one year or more years of college. The Waves being accepted for the Hospital Corps of the Navy are a true cross section of young womanhood in America and represent rural communities, large cities, factories, farms and schools. Their work is vitally important in that it releases male hospital corpsmen for sea or foreign service.

ADDITIONAL FACILITIES FOR CONVALESCENTS

The assistant chief of the Bureau of Medicine and Surgery, Rear Admiral Luther Sheldon Jr (MC), USN, it was announced on August 9, will inspect naval convalescent hospital facilities and equipment in the eighth, eleventh, twelfth and thirteenth naval districts and will examine various sites for their possible use as additional convalescent hospital expansion. Commander Francis I Braceland (MC), USNR, of the neuropsychiatry section, division of physical qualifications and records, who will accompany Admiral Sheldon, will examine the facilities available for navy neurologic cases in the inspection area.

CLASS IN DEEP DIVING

The Bureau of Medicine and Surgery announces that a class in deep diving for medical officers will be assembled at the Diving School, Navy Yard, Washington, D C, on September 13, and that twelve medical officers have been assigned to this instruction.

LIEUTENANT McCAMPBELL CITED

The commander of the South Pacific Area and South Pacific Force has commended Lieut (jg) Bruce R McCampbell, MC, USN, for service set forth in the following citation: "For skilful and effective performance of duty while serving on board a destroyer which participated in the engagement with Japanese forces off Guadalcanal, British Solomon Islands, on Aug 7, 1942. As medical officer of the vessel he rendered skilful aid to members of the crew who were wounded by enemy bombs. When his ship picked up four hundred survivors, more than half of them were in need of medical aid. By untiring efforts he rendered emergency treatment to two hundred and fifty persons in forty-five hours. His zealous conduct was in keeping with the highest traditions of the Naval Service."

Lieutenant McCampbell graduated from the University of Tennessee College of Medicine in 1941, was a student intern for two years at the U S Marine Hospital in Memphis, Tenn, and was an intern at the Naval Hospital, San Diego, Calif. He was promoted to the rank of lieutenant in March 1943.

PRISONERS OF THE JAPANESE

Lieut Mack L Gottlieb, MC, USN, formerly of New York, was captured by the Japanese while serving at the naval hospital in Guam and is now a prisoner of war at Zentsu War Prison Camp at Shikoku, Japan. Dr Gottlieb graduated from New York University College of Medicine in 1930, is a member of the American College of Physicians and the American Medical Association, and has been granted a certificate by the American Board of Internal Medicine.

According to *Northwest Midway*, Lieut Comdr Clyde I Welsh of Seattle, reported missing since July 1942, is declared a prisoner of the Japanese, probably in the Philippines. When action began in the Philippines he was stationed at Cavite Hospital, near Cavite.

MISCELLANEOUS

RECOMMENDED STANDARD FOR HOSPITAL SHEETING

The National Bureau of Standards, Washington, D. C., has circulated to the industry for written acceptance a recommended commercial standard for hospital sheeting for mattress protection (nonrubber), TS-3551, adopted at a meeting of a committee representing the American Hospital Association with a committee of manufacturers. This recommended commercial standard is being circulated to producers, distributors and users of hospital sheeting for written acceptance as a basis for publication by the National Bureau of Standards. This recommended commercial standard as adopted by the committee goes into such general requirements as fabric, material and workmanship, resistance to mineral oil resistance to disinfectants and sterilization, water permeability, resistance to cracking, burning rate, thickness, width and length and tearing strength and also briefly outlines the methods of testing for these requirements.

CINCHONA BARK IMPORTS RISE SHARPLY

According to the Office of the Coordinator of Inter-American Affairs, expansion of cinchona bark production in South and Central America is helping replace the loss of quinine supplies in the Far East. Cinchona bark production from Latin America is increasing steadily. In June cinchona imports from the other Americas were more than twice the average of the previous five months.

Development projects include preparation for distributing 3,000,000 cinchona seedlings from the El Porvenir plantation in Guatemala, the largest in the Western Hemisphere. This is part of the program to supplement collection of bark from wild trees. The large June imports of cinchona came from Bolivia, Peru, Ecuador and Colombia and from other scattered sources. The El Porvenir plantation with about 1,000 acres of cinchona, could supply a substantial portion of the entire United States quinine needs for a considerable period if all the trees were cut down. A number of trees are being weeded out under scientific forestry methods. The bark of these trees will be shipped immediately. Meanwhile the 300,000,000 seeds will be put in beds. Seedlings will be set out in Guatemala.

Use is being made of 2,000,000 cinchona seeds brought out of the Philippines by Col. Arthur F. Fischer. Of these 200,000 have been planted and have developed into seedlings at the Beltsville, Md., station of the U. S. Department of Agriculture. It is planned to put the rest into seed beds and then into nurseries in Costa Rica.

In Peru, bark from the wild trees is being collected on a large scale, and work is progressing on a plantation near Tingo Maria, Peru, east of the Andes. The United States is aiding this plantation with financial and technical aid.

MEDICAL SUPPLIES ON U. S. SHIPS

Ships sailing under the control of the War Shipping Administration which do not have ship's doctors aboard henceforth will be stocked with a revised minimum standard supply of drugs and medical supplies prescribed by the United States Public Health Service. It was announced on August 7. The revised edition of 'Ship's Medicine Chest and First Aid at Sea' published by the United States Public Health Service lists ninety-nine standard articles and how to use them. The list includes a variety of recognized medical supplies. Forty-six of the prescribed items such as phenobarbital, sulfanilamide and sulfathiazole, are listed as drugs. Although War Shipping Administration operated ships almost always travel in convoy, which always affords doctors the administration is now in the midst of a training program which will eventually provide pharmacist's mates aboard all merchant ships. In addition, all officers are required to pass an extensive first aid course. The administration states that the items it listed as standard were considered minimum for the protection of the crew. Agents will be permitted to add additional items which they consider advisable.

PUBLIC HEALTH UNDER HITLER

According to NPD, Germany, June 1, a new typhus institute under the direction of Prof. Dr. Hoffmann and equipped with the most modern appliances has been opened in Berlin.

It is reported from the commune of Garany, Zemplen County, according to *Régió Magyarorszag*, Hungary, on April 21 that plague has broken out among the half-year old pigs which have not yet been inoculated.

NPD Germany June 5, reports that during the past year seven new children's hospitals have been established in East Prussia alone besides these, six new nurses' training schools have been opened.

NPD of May 29 reports from Minsk that the German civil administration of White Ruthenia announces that a medical university (Hochschule für Medizin) will be founded in Moghilev for the training of medical students there. To begin with, German professors will be at the head of this university. The medical installations for the institute have already arrived from Germany.

According to *Hr.atski Narod* April 29, last year 1,101,037 inspections and 317,436 detailed examinations were carried out in Croatia. Spotted typhus was proved in 10,509 cases, 712 of which proved fatal. Stomach typhus in 5,099 cases with 453 deaths. Eighteen new health centers, organized to combat this disease, disinfected 231,134 persons as well as 134,266 railway carriages. Quarantine institutions were organized in Besanski-Brod, Siskak and Dugoselo, and twenty-two provisional hospitals have been erected for infectious diseases. The cost of these undertakings amounted to 143 million kuna, of which 35 was spent on personnel and 108 on materials.

NZ June 25 reports that the health of expectant mothers may be endangered if because of the great distance of their home from their work, they have to use means of transport which involve a great deal of vibration. In such cases the reich minister of labor has decreed that an inquiry be made whether the expectant mother should not be directed to a suitable job at a more favorably situated place of work. The inquiry will be carried out by the Labor Office which will arrange a transfer if the circumstances warrant it. In order that the expectant mother's first job may be kept for her she may be given leave or absence for the period of her transfer.

DNB June 28 reports that the reich minister of labor has directed that expectant mothers and women in childbirth who have lost their job through the closing down of the establishment or through enemy action are to be granted the increased confinement benefits (confinement allowance, nursing allowance and so on) in accordance with the Law for the Protection of Mothers if they could have claimed confinement benefit had the job not come to an end. The amount of the confinement allowance depends on the amount of the last wages earned by the expectant mother. The order was to come into force on July 1. The increased benefits will be granted retrospectively from the beginning of the period for which the expectant mother can claim benefit.

Brüsseler Zeitung June 5 in its report of Reeder's speech, reproduces the following statement on the general health situation of the Belgian population: England who cuts off Belgium from her food supplies feels obliged to complain about the bad state of health, the increased tuberculosis among Belgian children and adults and that at a time when explosive toys are being dropped from British airplanes on Germany and Italy.

All possible care and precautions are taken against diseases migrating westward such as scarlet fever and diphtheria. On January 1 it was stated that tuberculosis is only 10 per cent higher than it was before the war. This increase is easily attributable to war circumstances.

The *Vienna Wiener Tagblatt* June 24 states that according to the Vienna *Rathesamtliche* the number of cases of scarlet fever has recently considerably increased in Vienna as in the rest of Europe. In order to ward off this danger Stadtrat Professor Gundel of the central health office of Vienna has ordered the closing of all Volkskinderhauptkutschschulen and höhere Schulen. All children between the ages of 2 and 18 will be vaccinated against scarlet fever and diphtheria.

ORGANIZATION SECTION

OFFICIAL NOTES

LECTURE-OBSERVATION-DEMONSTRATION COURSE IN HEALTH EDUCATION

From August 2 through August 6 twenty-nine graduate students under fellowships from the W K Kellogg Foundation and the supervision of the United States Public Health Service spent a week of observation, study and demonstration of the health education and related work of the American Medical Association at the Association headquarters building in Chicago.

The following features were covered in the program

Monday, August 2 Announcement of week's plans, division into groups, distribution of reference packets, history of the American Medical Association, organization and work of the American Medical Association, tour of the Association building, health education in industry

Tuesday, August 3 Radio and health education, including demonstrations by transcription of radio interviews and dramatizations, tour of NBC and Blue Network studios

Wednesday, August 4 The work of the following departments of the American Medical Association, presented in each instance by its director: Bureau of Investigation, Council on Pharmacy and Chemistry, Press Relations and Medical News, *Hygeia*, the Health Magazine, *Hygeia* reprints and pamphlet publications, health meetings and speakers

Thursday, August 5 Journal publications and library services of the American Medical Association, group demonstrations of the organization and work of the Bureau of Health Education, guided tour of Chicago Museum of Science and Industry

Friday, August 6 Traveling exhibits for the public, scientific exhibits, motion pictures, answering health questions by correspondence, summary and conferences

Each student was furnished with an extensive collection of reference materials and each was given opportunity for personal consultation with the head of that Association department whose work most interested the student

MEDICAL ECONOMIC ABSTRACTS

THE HEALTH PROGRAM OF THE U S BUREAU OF CENSUS

The United States Bureau of Census is located in a Maryland suburb 6 miles from Capitol Hill, Washington, D C. Owing to the fact that the census is collected only every ten years, there is a great fluctuation in employment. During the census period there may be as high as 10,000 employees, but at present only 700 are classified as permanent. Eighty per cent are females and about 65 per cent white persons.

On Sept 1, 1942 Dr Leon Schwartz of the United States Public Health Service was assigned to the Bureau of Census to organize and conduct a health program. The program involves accurate absenteeism records, checked not only by the medical staff but by home visiting of all ill employees, for the preventive side the medical officer is readily available for medical advice, a program on medical education is conducted, necessary inoculations are given and sanitation of all work places is to be maintained at a high standard.

A laboratory and technical service will provide a minimum diagnostic service, the results of which will be made available for the use of the employees' private physician. Disability occurring during the work day will usually be treated within the emergency room with opportunities for rest available. Disabilities outside the building are generally referred for treatment to an outside physician. Because of the isolated location of the building it is probable that some therapy will be given at the place of employment. Office hours will be for consultation from 9 a m to 5 30 p m daily except Sundays.

CARE OF MEDICALLY INDIGENT IN NEW YORK CITY

A report of the Committee on Medical Economics of the Medical Society of the County of New York, adopted by the Committee Minora, offers a plan for the care of the medically indigent containing some new features.¹ A nonprofit agency is to be set up with the membership of the board of directors divided equally among city officials, physicians of the five county medical societies of Greater New York and prominent citizens acceptable to the first two classes represented. Physicians are to receive \$2 per house visit and \$1 per office visit. A central municipal registration bureau is to be established and the city districted with a medical panel for each district to which all licensed doctors of medicine are eligible. Arrangements are made for a specialist's care. Diagnostic tests are to be provided in clinics without charge.

Medical indigence is defined to include single persons who have an annual income of \$1,000 or less, \$1,450 for man and wife and \$250 for each dependent, not to exceed \$1,950 per family.

The chief executive is to be a paid physician.

Panel calls except for emergency are to be received between 8 a m and 8 p m. Patients treated after those hours will be charged an additional fee.

¹ Recommendations for the Care of the Medically Indigent. *Surgeon* 98:56 (July 16) 1943.

WOMAN'S AUXILIARY

California

For some time women of the Los Angeles County Medical Auxiliary have been coming together to do Red Cross work. Now they have their own Red Cross unit. Another project of this auxiliary was the furnishing of four day rooms at Camp Santa Anita. Dr William R Molony Sr, president of the California Medical Association, and Mr Manuel Aguilar were guests of honor at the January meeting.

The San Benito County auxiliary, with a membership of only 6, sponsored a dancing party in San Juan which netted them \$495.60. This money was used to furnish a room in the

Hazel Hawkins Hospital, Hollister, to be used by the Red Cross.

Oklahoma

The Oklahoma County medical auxiliary met in the Ventron Room of the Y W C A in Oklahoma City and sewed on layettes, which were placed at the disposal of the city hospitals. The special project of the auxiliary this year is the making of troop trains and serving the boys gum, candy and cigarettes. Of 32 members interviewed, it was found that they had averaged more than one hundred hours each in war service. Mrs R O Early tops the list with eight hundred hours.

Orchestra Founded by Physician.—For thirty nine years members of an orchestra started by Dr Leonard G Stanley, Albany, have been meeting every Thursday night except during June, July and August. The orchestra has never given a public performance. At one time the orchestra included with Dr Stanley three physicians one of whom was the late Dr Hoard E Lomax of the Albany Medical College. Dr John H Gutmann, Albany, retired because of ill health. Dr Stanley, who is 73 years of age, is the conductor of the group.

Hospital News—Construction started, June 15, on a new \$40,000 addition to the Margaretville Hospital, Margaretville. The addition will increase the bed capacity from twelve to twenty-five single rooms and will also include two 6 bed wards, two new nurseries, a new operating room suite and a new delivery suite as well as a modernized laboratory and diagnostic facilities. The addition will bring to the top bed capacity to 62 beds in case of emergency with a normal quota of 37. Funds for the new addition are being raised through popular subscription and it is expected that the construction will be completed about December 1. Dr Gilbert M. Palen has been appointed chief of the medical and surgical staffs and Dr Gilbert J. Palen superintendent. The Sister Elizabeth Memorial, first maternity hospital in Bay Ridge, was dedicated on July 11, the hospital is a division of the Norwegian Lutheran Deaconesses Home and Hospital, Brooklyn, and was named in honor of the first head deaconess of the hospital, the late Sister Elizabeth. It has 40 beds and eight nurseries and was equipped at a cost of about \$110,000.

New York City

Nutrition Center Opened—A food and nutrition center, to be the headquarters of the New York City Food and Nutrition Program, was formally opened on July 28 at 45 Lafayette Street, Manhattan. The center primarily will be an information bureau where persons may receive free nutrition advice keyed to the latest wartime market conditions. It will also serve as a center where the contributions of the participating agencies can be made available to the public. Dr Ernest L. Stebbins, city health commissioner, presided at the opening and speakers included Mayor Fiorello H. LaGuardia and Grace MacLeod, Ph.D., professor of nutrition at Teachers College.

Grant to Aid Neuropsychiatric Rejectees—The State Charities Aid Association has received a grant of \$19,000 from the Commonwealth Fund to enable its city mental hygiene commission to prepare a plan for aiding men rejected or discharged by the armed forces because of neuropsychiatric conditions. The money became available on July 1. In a statement to the press, as reported in the *New York Times*, July 10, Homer Folks, secretary of the State Charities Aid Association, suggested that the problem of providing psychiatric and other needed help for rejected and discharged men was of too great magnitude for any voluntary organization or organizations to solve. At the same time the State Charities Aid Association "might perform a very useful service in defining much more clearly the extent and character of the need of these two groups of men, determining what sorts of help are needed, how such help could be provided by some public authority, and what the cost would be."

NORTH CAROLINA

Special Society Election—Dr Romulus L. Carlton, Winston-Salem, was elected president of the North Carolina Tuberculosis Association at its meeting in Raleigh recently. According to the state medical journal, other officers include Dr David T. Smith, Durham, vice president, Dr Joseph J. Combs, Raleigh, treasurer, Mrs Marie B. Noell, Raleigh, secretary, and Frank W. Webster, Raleigh, executive secretary.

Personal—Sterling Brackett, Ph.D., assistant professor of public health in the School of Public Health of the University of North Carolina, Chapel Hill, has been appointed malarialogist in the Stamford Research Laboratories of the American Cyanamid Company, Stamford, Conn.—Dr Charles W. Banner, Greensboro, was honored recently when a large portrait of him was presented to the L. Richardson Memorial Hospital, Greensboro. Dr Banner is chairman of the board of trustees of the hospital.

OHIO

Opposition to Medical Program for Families of Service Men—At a meeting, July 11, the council of the Ohio State Medical Association adopted a statement of policy, recommending methods of assisting needy wives and infants of enlisted men in the armed forces to obtain financial assistance for medical and nursing services and hospitalization, if the need for such financial assistance arises, and opposing a plan proposed by the U. S. Children's Bureau for the establishment of a federally financed and supervised medical program in Ohio. Before the use of public funds or the maintenance of a government controlled medical program to furnish this type of service is made necessary, the association recommends cooperation with the army emergency relief and similar agencies in other services which already have funds available for immediate need. In offering its recommendations the Ohio State Medical Association urges its members to see "that all persons regardless of financial status shall be provided with an opportunity to utilize the advantages of modern scientific medicine" at this time.

PENNSYLVANIA

Protest Appointment of Layman in Health Job—Physicians have been protesting to their local societies against the appointment by Governor Martin of Carl C. Tinstman, Forty Fort, as deputy secretary of health. The Dauphin County and Perry County medical societies have adopted resolutions protesting to the state medical society the selection of a layman for this position, which has been filled by a "medical man" since the creation of the state health department in 1905.

Philadelphia

Osler Medal Goes to Pennsylvania Student—The American Association of the History of Medicine has awarded the William Osler Medal to Dr George E. Murphy, Kansas City, Kan., 1943 graduate of the University of Pennsylvania School of Medicine, in recognition of his essay "The Evolution of Our Knowledge of Rheumatic Fever." The essay is to be published in the *Bulletin of the History of Medicine*. The Osler Medal was established in 1941 to be awarded for the best student essay submitted to the association (*THE JOURNAL*, Oct 25, 1941, p. 1482).

Dean Sturmer Retires—Julius W. Sturmer, Ph.D., has retired as dean of the Philadelphia College of Pharmacy and Science after serving in this capacity since 1916. After Dr Sturmer graduated at Purdue in 1891 he served for a number of years as a member of the faculty. In 1912 he became professor of pharmacy and dean of pharmacy at the Medico-Chirurgical College of Philadelphia. In 1916, after the merger of this college with the University of Pennsylvania and following an agreement with the Philadelphia College of Pharmacy involving the transfer of pharmacy students of the Medico-Chirurgical College to the Philadelphia College of Pharmacy, Dr Sturmer became professor of pharmaceutical chemistry and a dean in the latter institution. With the establishment of the curriculum in chemistry, bacteriology and biology in 1921 the college changed its title to the Philadelphia College of Pharmacy and Science and Dr Sturmer became its dean of science.

RHODE ISLAND

Medical News to Merge with State Journal—The *Providence Medical News* suspended publication with its July issue to merge with the *Rhode Island Medical Journal*. The Providence Medical Association published its first journal in January 1900 as a quarterly, relinquishing its ownership in 1917 in order that the journal might become a monthly publication under the auspices of the state medical society. In May 1939 the association created the *Providence Medical News*, and it is this publication that is now being combined with the state medical journal.

No Award of Fiske Fund—The *Rhode Island Medical Journal* has announced that the income of the funds making up the Fiske Award is not enough to offer any premium this year or to carry on any of the former activities of the fund. The money was left by Dr Caleb Fiske to encourage original work on the part of the members of the society. Amounting to \$12,000, these funds are invested by court order in such a way that the income, under present conditions, is almost negligible. The trustees are attempting to have the investments changed to bring about a reasonable return, assuring the continuance of the fund's work next year.

State Medical Election—Dr Elihu S. Wing, Providence, is the president-elect of the Rhode Island Medical Society and Dr Michael H. Sullivan, Newport, chosen vice president, was elevated to the presidency, filling the vacancy that occurred with the death of Dr Murray S. Danforth, Providence, three days after his installation as president of the society. Dr James L. Wheaton, Pawtucket, was named vice president. Dr William P. Buffum, Providence, is the secretary, Dr Albert L. Potter, Providence, assistant secretary and Dr Jesse E. Mowry, Providence, treasurer. Mr James E. Farrell is the new executive secretary. Dr Edwin H. Place, professor of clinical pediatrics, Tufts College Medical School, Boston, delivered the annual Charles V. Chapin Oration during the meeting on "Changing Views of the Contagious Diseases." Other speakers on the program included

Dr Anthony V. Mighaccio, Providence, Report of Six Cases of Meckel's Diverticulum
Lieut. Col. Marshall A. Fulton, M.C., A.U.S., The Problems of an Army General Hospital
Major Clarence E. Bird, M.C., A.U.S., The McBurney Incision
Dr Alexander T. Martin, New York, Rheumatic Fever in Childhood Its Recognition and Management

TENNESSEE

Dr Christie Succeeds Dr Casparis—Dr Amos Christie, a staff medical director of the American Red Cross, Washington, D. C., has been appointed professor of pediatrics at Vanderbilt University School of Medicine, Nashville, succeeding the late Dr Horton R. Casparis. Newspapers report that Dr Christie will begin his new work on October 1. Prior to his appointment with the Red Cross, Dr Christie had been connected with the University of California Medical School, San Francisco, since Sept. 1, 1930 and most recently as associate professor of pediatrics. He had also been a member of the California State Board of Health and once served as specialist in pediatrics with the U. S. Children's Bureau.

TEXAS

Dr Thompson Made Member Emeritus—At the recent annual meeting of the State Medical Association of Texas, Dr William R. Thompson of Fort Worth, was elected a member emeritus of the association. Dr Thompson is the only living member of the original board of trustees of the association, having been a member since 1904. He had been secretary of the board of the association from 1905 to 1942.

Memorial Library Funds—Dr Hudson L. Taylor, Houston, immediate past president of the State Medical Association of Texas, jointly with Mrs. Taylor has set up two memorial funds for the support of the Texas Memorial Medical Library Association. One fund commemorates the medical service of Dr Taylor's brother, Dr Martin Junius Taylor, now living in Houston, and the other is in memory of Mr. and Mrs. William Thomas Carter, the parents of Mrs. Taylor.

Construction on Cancer Project—The clinic buildings for the M. D. Anderson Cancer Research Hospital are being erected at 2310 Baldwin Avenue, Houston, where the old Baker Home has been in use for quarters of experimentation for the last three months. The *Texas State Journal of Medicine* reported in July: There will be three buildings, a reception center, an animal house and a biochemistry building, all of which are expected to be available within the next three months.

Lectureship in Ophthalmology to Honor Dr McReynolds—Mrs. F. W. Wozenrafft, Washington, D. C., has presented a fund to establish a lectureship in ophthalmology at the University of Texas Medical Branch, Galveston, in honor of her father, Dr John O. McReynolds, who died on July 7, 1942. Dr McReynolds, who entered private practice in Dallas in 1892, was Vice President of the American Medical Association in 1926-1927 and chairman of the Section on Ophthalmology, 1922-1923.

Storm Forces Cancellation of Graduation Exercises—The fifty-third graduation exercises of the University of Texas Medical Branch, Galveston, scheduled for Saturday, July 31, were canceled because of the damage caused by a tropical storm, according to an announcement from Chauncey D. Leake, Ph.D., dean. Degrees were conferred on August 2 just prior to the beginning of the state board examinations and diplomas were presented August 4 at an informal meeting at which Dr. Witten B. Russ, San Antonio, spoke on "The Doctor and the Postwar World."

UTAH

State Medical Meeting—At the annual session of the Utah State Medical Association at the University of Utah, Salt Lake City, August 27-28, speakers will include:

Dr. Emil G. Holmstrom, Salt Lake City: Treatment of Carcinoma of the Cervix Uteri.
Dr. Adelbert Louis Dippel, Minneapolis: Some Aspects of a State-wide Maternal Mortality Study.
Lieut. Col. James S. Sweeney, Paris, Texas: M. C. A. U. S. The Peptic Ulcer Syndrome in Patients Without Radiographic Evidence of Ulcer.
Major Rudolph A. Kocher, Carmel, Calif.: M. C. A. U. S. Malaria in Soldiers Returned from the Southwest Pacific.
Lieut. Col. Henry G. Hollenberg, Little Rock, Ark.: M. C. A. U. S. Treatment of Wounds—Consideration of General Nutritional Disturbances and New Therapeutic Agents Such as Penicillin.
Dr. John Z. Brown, Salt Lake City: Report of Delegate to the American Medical Association.
Dr. Lynne A. Fullerton, Denver: Senior Surgeon, U. S. P. H. S. Some Public Health Problems in Utah.
Lieut. Col. Harold R. Hennessy, Salt Lake City: M. R. C. U. S. Army: The Industrial Medical Program of the United States Army.
Dr. Philip B. Price, Baltimore: Hand Disinfection.
Lieut. Col. John B. Flick, Bryn Mawr, Pa.: M. C. A. U. S. Treatment of Burns.
Lieut. Col. Verne R. Mason, Los Angeles: M. C. A. U. S. and Major William J. Mitchell, Los Angeles: M. R. C. U. S. Army: Therapeutics in Army Hospitals.
Lieut. Woodrow W. Scher, Manhasset, N. Y.: M. C. A. U. S. Aviation Medicine—Problems of High Altitude Flights.
Dr. Fuller B. Bailey, Salt Lake City: Diarrhea.
Lieut. Col. Olin B. Chamberlain, Charleston, S. C.: M. C. A. U. S. The Concept of Psychosomatic Medicine.

WISCONSIN

State Medical Meeting—The one hundred and second annual meeting of the State Medical Society of Wisconsin will be held in Milwaukee, September 13-15, under the presidency of Dr. Russell M. Kurten, Racine, with sessions in the Milwaukee Auditorium and Hotel Schroeder. The program will include the following out of state speakers:

Dr. Frank C. Mann, Rochester, Minn.: Physiology of the Liver.
Dr. Cecil J. Watson, Minneapolis: Studies of Liver Disease with Correlation of Clinical Features and Liver Function Tests.
Dr. Marion A. Blankenhorn, Cincinnati: Differential Diagnosis of Jaundice.
Dr. Warren H. Cole, Chicago: Surgical Advances from the War.
Rear Admiral Ross T. McIntire, surgeon general of the U. S. Navy: The Navy's Demand on the Scientific Training of the Medical Officer.
Dr. George B. Eusterman, Rochester: The Relation of Peptic Ulcer to Cancer of the Stomach.
Dr. Donald C. Baltour, Rochester: When Is Peptic Ulcer a Medical and When Is It a Surgical Problem?
Dr. Frederick A. Collier, Ann Arbor, Mich.: Transfusions and Fluid Balance.
Dr. John Romano, Cincinnati: Psychiatric Problems Arising from Military Service.
Dr. Claude F. Dixon, Rochester: Diagnosis and Treatment of Cancer of the Bowel.
Dr. John S. Coulter, Chicago: Medical Aspects of Chemical Warfare.
Dr. William A. O'Brien, Minneapolis: Problems Concerning Graduate Education and Employment of Nurses, Interns and Residents.
Mr. J. W. Holloway, Jr., director, Bureau of Legal Medicine and Legislation, American Medical Association, Chicago: Hospitals in the Selection of Medical Staffs.
Father Alphonsus M. Schwitala, S. J., Ph.D., St. Louis: Future Joint Problems of Medicine and the Hospitals.
Dr. Chauncey C. Maher, Chicago: Recognition of Early Myocardial Failure.
Dr. Paul S. Rhoads, Evanston, Ill.: Rheumatic Fever: Diagnosis and Treatment.
Dr. Ralph A. Reis, Chicago: Sterility.
Dr. Sanford R. Gifford, Chicago: The Eye in General Diagnosis.
Dr. Hart E. Van Riper, Washington, D. C.: Better Health for Children: Physicians and the Social Security Program.
Dr. Paul H. Holinger, Chicago: The Infant Larynx.
Dr. Edgar J. Huenekens, Minneapolis: Immunization in Pediatrics Practice.
Dr. Leo M. Zimmerman, Chicago: Improved Surgical Treatment of Hernias.
Dr. James B. Brown, St. Louis: Plastic Surgery.
Dr. Dean M. Lierle, Iowa City, Iowa: Acute Upper Respiratory Infections and Their Control.
Dr. John L. Emmett, Rochester: Treatment of Urinary Stones.
Dr. Charles D. Creevy, Minneapolis: Urinary Diagnosis.
Capt. William E. Eaton (MC), U. S. Navy: Ulcer Problem in the Armed Forces.

GENERAL

Infantile Paralysis Fund Collections—A total of \$5,527,590.99 was collected in the annual appeal for infantile paralysis funds, exceeding by more than 30 per cent all previous collections. The total was \$1,500,000 higher than any previous year. Expenses were \$147,871.41, or only 2.6 per cent of the collections less than half the cost in any other year in the decade that President Roosevelt's birthday has been dedicated to the fight against poliomyelitis according to the National Foundation for Infantile Paralysis.

Fourth of July Deaths Reduced—Reports assembled by the Associated Press indicated that the traffic deaths throughout the nation over the Fourth of July weekend dropped by more than half as compared to last year while railroad travel reached record proportions according to the *New York Times*. The tally of highway fatalities was 131 as against 320 last year and 500 in 1941 which was before the institution of gasoline rationing. Deaths due to fireworks were reduced to zero. The total of deaths from all causes was listed as 307, 89 of the remainder being drownings and the rest miscellaneous.

Prize for Paper on Glaucoma—The National Society for the Prevention of Blindness announces that a prize of \$250 will be awarded for the most original paper adding to the present knowledge about medical treatment of noncongestive glaucoma. This prize is being offered in addition to one that was previously announced for the most valuable original paper concerning the early diagnosis (THE JOURNAL, Dec. 12, 1942, p. 1238). Papers may be presented by any practicing ophthalmologist in the Western Hemisphere and may be written in English, French, German, Italian, Spanish and Portuguese but any of those written in the last four languages should be accompanied by an English translation. The award will be made by the society with the guidance of an ophthalmologic committee. Papers should be in the office of the society, 1790 Broadway, New York, by September 1944.

National Research Council Fellowships—Recent fellowships announced by the medical fellow ship board of the National Research Council, Washington, D. C., include the Welch fellowships in internal medicine to Dr. Sinclair Howard Armstrong, Jr., Harvard Medical School, Boston, and Dr. Joseph F. Ross, Robert Dawson Evans Memorial Hospital, Boston. A fellowship in the medical sciences was renewed for Dr. Lester

J Talbot at the New York University College of Medicine, and one for orthopedic surgery for Dr Maxwell F Kepl at Tulane University of Louisiana, New Orleans. Fellowships in filtrable viruses were awarded to Edward H Anderson, Ph D, Vanderbilt University, II Chandler Elliott, Ph D (renewal), University of Toronto, Dr I William McLean Jr, Duke University School of Medicine, Dr Alison H Price, University of Michigan (declined appointment), Dr Hugh Tatlock, Yale University School of Medicine, New Haven, Conn, and the Acute Respiratory Diseases Commission Laboratory, Fort Bragg, N C, and Dr Herbert A Wanner, Yale University School of Medicine and Johns Hopkins University.

Distribution of Excessive Poliomyelitis—The following tabulation presents the available figures for areas in which poliomyelitis is known to have reached excessive proportions

	Cases Reported 1943 up to Aug 7	Cases Reported Week Ended Aug 7
1 Alabama	46	6 (July 31)
2 California	952	111
Kern County (week ended July 31)	103	46
Los Angeles County (week ended July 31)	231	28
3 Connecticut	41	24
New Haven County	34	20
4 Kentucky	51	8
5 Oklahoma	292	62
6 Texas	757	62
Dallas County (week ended July 31)	60	10
Harris County (week ended July 31)	81	10
Tarrant County (week ended July 31)	80	12

There is reason to believe that the incidence of poliomyelitis may be considerably above normal in some other areas, notably Kansas, but figures for Kansas were not available.

Other areas under suspicion are

	1943 to July 24	Week Ended July 24
Washington	22	2
	1943 to Aug 10	Aug 1 to Aug 17
Illinois	131	124
Cook County		113

Congress of Physical Therapy—The American Congress of Physical Therapy will hold its twenty-second annual session at the Palmer House, Chicago, September 8-11. At the formal opening the speakers will include Drs Kristian G Hansson, New York, on "Physical Therapy in Wartimes" and Eben J. Carey, Milwaukee, "Physical Therapy in Medical Education." Among the other speakers on the program will be

Capt Sidney H Licht and Capt Vernon S Dick, M C, A U S, Sulfadiazine and Fever Therapy in Resistant Gonorrhea.
Lieut Comdr Kenneth Phillips (MC), U S Naval Reserve, and Ensign Alice B Mundorff (NC), U S Naval Reserve, The Reduction of Man Power Loss from Gonorrheal Urethritis by the Early Application of Chemo Fever Therapy.
Lieut Arthur Price, M C, A U S, Renal Complications in Combined Sulfathiazole Fever Therapy.
William Firth Wells, B Sc, Philadelphia, Radiant Disinfection.
Drs George P Miles, Jens Allen Christensen and Raymond Edwin Seidel, Philadelphia, A Preliminary Report of Results Observed in Eighty Cases of Intractable Bronchial Asthma.
Dr Robert Talbot McElvenny, Chicago, Refrigeration.
Dr Bayard T Horton, Rochester, Minn, Peripheral Vascular Disease.
Dr Hans J A Behrend, New York, Modern Hydrotherapy II A.
Review of Recent Developments.
Dr Carl E Badgley, Ann Arbor, Mich, Rehabilitation of Arthrogryposis Multiplexa Congenita.
Dr Edward L Compere, Chicago, Management and Care of Infantile Paralysis Patients.
Dr Midge C L McGuinness, New York, Rehabilitation, Prehabilitation and Placing the Recovered Workman.
Dr Alfred P Solomon, Chicago, Psychiatric Orders for Rehabilitation Physical Therapists.
Dr Edward C Holmblad, Chicago, Rehabilitation of Injured Workers in Small Plants.
Dr Geza de Takats, Chicago, Sudeck's Atrophy—A Chronic Vasodilator Mechanism.
Dr Jessie Wright, Pittsburgh, Mechanics in Relation to Derangement of the Facet Joints in the Spine.
Dr Clarence A Neymann, Chicago, Some Thoughts About Shock Therapy.
Dr John A Aita, Rochester, Electric Shock Therapy, Its Indications and Use.
Dr Edgar V Allen, Charles Sheard, Ph D, and Grace M Roth, Ph D, Rochester, The Interpretation and Clinical Significance of Calorimetric and Skin Temperature Measurements of the Extremities.
Brig Gen Frank T Hines, Washington, D C, Rehabilitation in the Veterans Administration.
Major Ora L Huddleston, M C, A U S, Use of the Convalescent Ward in the Rehabilitation and Disposition of Disabled Soldiers.
Lieut Comdr Jacob L Rudd (MC), U S Naval Reserve, Rehabilitation of War Wounded in a Physical Therapy Department of a Navy Hospital.
Dr Frank H Krusen, Rochester, Physical Rehabilitation and the War.
Lieut Comdr Louis B Newman (MC), U S Naval Reserve, Organization and Management of a Navy Physical Therapy Department.
Dr Warren H Cole, Chicago, The Treatment of Shock, With Special Reference to Heat and Cold.
Dr Harry E Mock, Chicago, Rehabilitation in Head and Back Injuries.

There will also be a symposium on "Rehabilitation of the Child," an instruction seminar, and demonstration. Additional information may be obtained from the executive director, American Congress of Physical Therapy, 30 North Michigan, Chicago.

LATIN AMERICA

The Brazilian Book of Honor—The name of Dr Vital Brasil, at one time inspector of public health in São Paulo and founder of the Vital Brasil Institute of Niteroi, Rio de Janeiro, for the preparation of serum and vaccines and for research work, has been added to the Brazilian "Book of Honor," established recently by Dr Getulio Vargas, president of Brazil, to preserve the names of great Brazilians for posterity.

Latin American Congresses—The seventh Argentine Congress of Medicine will meet in La Plata City, November 14-21. The headquarters of the congress are Calle 50 numero 374 La Plata, Argentina, S A.—The first Inter-American Congress of Radiology will meet in Buenos Aires during the last two weeks of October. Dr Jose F Merlo Gomez, the president of the Sociedad Argentina de Radiologia, and Dr Oscar F Noguera will be the president and general secretary, respectively. Drs Sabina di Rienzo of Cordoba, Luis Opazo and Leonardo Guzman C of Chile, Nelson de Carvalho of Brazil, Pedro A Maissa of Buenos Aires, Gonzalo Esguerra Gomez of Bogota and Oscar Soto of Lima will be official speakers. The headquarters of the congress are as follows: Secretaria General del Primer Congreso Interamericano de Radiologia, calle Alsina, 3317, Buenos Aires, Argentina, South America.

Establish Laboratory in Dominican Republic—Dr Enrique W Lithgow, who has for two years been associated with the pathology department of Mount Sinai Hospital, left New York on August 2 to establish a pathologic laboratory and postgraduate educational program in pathology in the Dominican Republic. Dr Lithgow's study at Mount Sinai has been financed by the Dazian Foundation. Recently Dr Fernando A Batlle, director of the Padre Billini hospital and president of the Cancer Institute in Trujillo City, invited Dr Lithgow to return to his native land to make available there the benefits of current advances in pathology. This invitation was supported by the Dominican government. He will take up research and educational activities at the Padre Billini Hospital and later at the Cancer Institute, which is to open in the near future. The fellowship under which Dr Lithgow is working is one of several granted annually by the Dazian Foundation under the presidency of Dr Emanuel Libman, consulting physician to the hospital, which are awarded to selected younger physicians of Central and South American countries for postgraduate study and research in the United States.

FOREIGN

Distribution of Medical Journals to Chinese Institutions—A case containing six sets of medical journals sent by the American Bureau for Medical Aid to China, recently received in Chungking, was distributed by Surgeon General Loo Chi-teh so that it will serve about eighteen separate institutions. One set went to the Emergency Medical Service Training Schools. Another was sent to Koloshan, where it will be available to the Shanghai Medical School, the National Institute of Health, the Central Hospital and the Nursing School. The set at Kweiyang will serve Hsiang Ya and Kweiyang Medical Schools, the Provincial Health Department and the Training Institute. To Chengtu went one set for the use of National Central Medical School, West China University, the Branch Training School, Provincial Health Department and the editors of the *China Medical Journal*. The Army Medical College at Anshun received a set while the remaining one went to the northwest for the training schools, Epidemic Prevention Bureau, Northwest Hospital and Kinus National Medical College. In this way the medical literature sent by the American Bureau for Medical Aid to China benefits the greatest possible number of people, according to an announcement.

Deaths in Other Countries

Sir Harold Beckwith Whitehouse, president of the British Medical Association, professor of midwifery and diseases of women, University of Birmingham, died in London on July 26, aged 60. According to the *New York Times*, Sir Harold collapsed on the street just after leaving the British Medical Association meeting, at which he had been nominated for the presidency for the second successive year. He died one hour later. In 1933 he was a visitor to the United States as the guest of the American College of Surgeons.

Foreign Letters

LONDON

(From Our Regular Correspondent)

June 15 (delayed)

The Army Blood Transfusion Service

The British army has a highly developed blood transfusion service. Its headquarters were established in England six months before the war and its plasma drying plant was erected in 1941. In England the service operates in 850 centers with a staff of 350, of whom more than three fourths are women. The original technical staff was drawn largely from the technical staffs of the Royal College of Surgeons and the Middlesex Hospital. The Army Blood Supply Depot has a panel of over 200,000 donors and collects 3000 pints of blood a week. The blood is issued to all theaters of war either as stabilized fluid plasma or as the dried product which keeps indefinitely. Whole blood of group O is supplied only to units which have a refrigerator. Before issue it is tested to make sure of the grouping and also to exclude syphilis. Blood banks consisting of blood dispatched from the central depot to a peripheral point need close attention to avoid undesirable reactions. Bank blood must never be allowed to warm until just before administration for a high proportion has been found to contain a few non-pathogenic organisms. Though insignificant as long as the blood is kept cool, they multiply rapidly on warming. The ideal temperature for the refrigerator is 4 to 6 C. Too low temperatures tend to cause rapid hemolysis.

The arrangements in the field are described in the Army Medical Department Bulletin. Where lines of communication exist, field transfusion units are supplied from the base. In addition all medical units carry a 'field medical box' containing transfusion fluids ready for immediate use. When lines of communication are interrupted, units which have exhausted their stocks of transfusion fluids and cannot get fresh supplies must collect blood from volunteers. The field transfusion box contains equipment for bleeding donors and for ascertaining their blood groups, but when it is anticipated that medical units will be working in isolation the whole personnel may be grouped in advance, so that any one can serve as a donor without further test. Similarly, certain combatant formations such as commando and air borne troops are grouped so as to minimize delay in finding donors suitable to each patient. When temporary isolation is expected, medical units can carry specially prepared large stocks of prepared fluids and further supplies may be dropped by parachute.

The European Association of Clinical Pathologists

One result of the war is much increased personal contact of our physicians with those of the allied countries who are refugees here. This has resulted in the formation of a new body the European Association of Clinical Pathologists which is to function permanently after the war. At a meeting held in London the following officers were elected: president Dr S. C. Dyke, England; vice president Prof E. J. Bigwood, Belgium; secretary, Dr F. Pick, Czechoslovakia; treasurer Dr B. L. Della Vida, Italy; council, Dr A. Benau, Yugoslavia; Dr D. C. Canne, Netherlands; Dr F. Duran Jorda, Spain; Prof F. Silberstein, Austria; Dr G. Ungar, France; and Dr J. Ungar, Czechoslovakia. The annual subscription including the entrance fee, is \$2. Rules were adopted for the association while its members are mainly in this country, and the council was instructed to consider the procedure to be adopted after the liberation of Europe. A resolution was passed to the effect that free interchange of workers in clinical pathology between the nations of Europe would be an important factor both in

the advancement of scientific medicine and in the development of a common European mentality, these being the main objects of the association. An invitation was received from the British Association of Clinical Pathologists inviting members of the European association to participate in its meetings. Membership is open to physicians of all European nationalities engaged in any form of medical laboratory work. Those interested are invited to communicate with the secretary, Dr Pick, Department of Clinical Pathology, General Hospital, Walsall, Staffs, England.

A British Hospital for Stalingrad

The archbishop of Canterbury, Lord Horder, Sir Gowland Hopkins and other well known persons have published an appeal for funds to build a new hospital at Stalingrad as "a permanent expression of the British people's gratitude to the defenders of Stalingrad, who have made such a great contribution to the final victory of the united nations." The Joint Committee for Soviet Aid is appealing for \$375,000 by June 22. The *British Medical Journal* suggests that if every one on the Medical Register should contribute \$4 this aim could be achieved without further contributions. But much more than the sum mentioned will be required to complete a hospital which will be a fitting memorial to the defenders of Stalingrad and at the same time play a large part in supplying the needs of that historic city.

Constantine Lambrinudi, A Great Orthopedic Surgeon

The death at the age of 53 of Constantine Lambrinudi has cut short the career of a leader in orthopedics much esteemed for his personal qualities. The son of a Greek stockbroker settled in London, he was educated at Cambridge and Guy's Hospital. His studies were interrupted by service in a Red Cross unit in the Greco-Bulgar campaign and then as an unqualified doctor in the Greek army. After qualifying in 1914 he joined the army of Venizelos. Toward the end of the first great war he became a medical officer in the British air force. In 1928 he was appointed assistant orthopedic surgeon to Guy's Hospital and in 1934 on the death of Mr. Trethowan, orthopedic surgeon in charge of the department. An original thinker on the lines of function he worked out the cause and correction of deformities. Present day views on the mechanism of the foot are due to his teaching. He is remembered for his operation for drop foot, his treatment of claw toes by arthrodesis, his operation for elevated first metatarsal with hallux rigidus and the use of Kirschner wires for fixing certain fractures. A keen advocate of correct posture, he was the first to show the connection between short hamstrings and adolescent kyphosis. As a teacher of orthopedics he was supreme. His originality and quick insight impressed those who had the good fortune to be his pupils. In a tribute published in the *Guy's Hospital Gazette* he is described as possessed of the power to see things anew with a vision entirely unprejudiced by established beliefs. He always laid stress on function and therefore instituted the employment of a visiting masseuse in hospital practice.

Faculty of Medicine of the University of Poland Within Edinburgh University

The Faculty of Medicine of the University of Poland was established within the University of Edinburgh for the exiled Poles so as to keep together professors, physicians and other medical workers to give them an opportunity for research and teaching and generally to promote the academic spirit so that after the war Poland would have at least one active medical school. All those in Poland were destroyed by the Germans. The project has been successful and a Polish hospital is attached to the school for clinical work. The course of study and the examinations are arranged in accordance with the

requirements of Polish law and at the same time to approximate as much as possible Edinburgh standards. A ceremony has taken place in which representatives of the University of Edinburgh and the Polish Faculty of Medicine attended. The president of the republic of Poland conferred the Order of Polonia Restituta on Sir Thomas Holland, vice chancellor and principal of the University of Edinburgh, Prof Sidney Smith, dean of the Faculty of Medicine, and Prof F A E Crew, who holds the chair of genetics. This was done in recognition of the great service rendered to Poland by the university in giving an invitation to found a technical school within its walls.

Social Trends in Australian Medical Practice

THE NEW ZEALAND SCHLME

Medical benefits as incorporated in the National Health and Pensions Act of 1938 and the report of the Federal Council of the British Medical Association in Australia have been discussed in previous letters. The third scheme for an Australian Medical Service under consideration is that now operating in New Zealand. The New Zealand Social Security Bill was passed in 1938. It was intended to provide a system of monetary and of medical, hospital and related benefits on a contributory basis. The scheme was financed by a new social security tax, which has been in operation since April 1939. Maternity, hospital, pharmaceutical, radiologic and medical benefits were instituted in this order during the period dated from April 1939 to December 1941. The general practitioner service originally promulgated in March 1941 was based on a capitation system. The medical profession refused to cooperate, and in December 1941 the government was forced to introduce an alternative 'fee for service' scheme.

The benefits now in operation include the following:

(a) **Maternity Benefits** Doctors receive £5-5-0 from a social security fund for each confinement with extra for anaesthetics. Recognized specialists are allowed to charge their usual fee and collect the difference from the patient. All practitioners except those who do not ordinarily practice midwifery are considered to be working under the scheme. The maternity hospitals normally receive £11 11s for each confinement, but some hospitals, by special permission of the government, are allowed to charge more.

(b) **Hospital Benefits** Public hospital services, including accommodation, maintenance and medical attendance, are free to all sections of the community. Public and private hospitals receive 6 shillings a day per occupied bed from the social security fund.

(c) **Pharmaceutic and Roentgenologic Benefits** Drugs and preparations appearing in the British pharmacopeia are free. Roentgenologic services at public hospitals are free, private radiologists charge a stipulated fee, of which the government and the patient each pay half.

(d) **General Practitioner Service** There are two schemes in operation. (1) Doctors may take at a capitation of 15 shillings a head per year up to 4,000 on a panel or (2) they may charge as much as 10/6 per service, of which 7/6 is paid from the social security fund. An extra charge is made for mileage in country districts. Only a very few medical practitioners work under the capitation system.

(e) **Specialist Services** These are free at public hospitals, private patients may claim 7/6 out of the usual specialist fee of £1 1s.

The New Zealand scheme is a socially valuable one in that it has ensured medical attendance for every member of the community. But, by stabilizing the economic aspect of medical

practice for both patient and professional, it has tended to establish medical efficiency generally at the level which existed prior to its introduction. In the latter respect the scheme is static, in that it offers no constructive policy for maintaining or improving the standard of medical practice, and retrogressive, in that it has done little to abolish preexisting evils of medical organization and administration. Under the scheme no help is given toward the cooperation of doctors in groups for mutual relief and better service. No provision is made for postgraduate training or large scale research operations and there is no comprehensive scheme for including the newer tendencies of modern preventive medicine in the general medical service. The deficiencies of the scheme are well exemplified by a consideration of hospital services. Many public hospitals, especially those in large cities, are out of date, ill equipped and not necessarily staffed by the best medical talent of the district. Owing to the shortage of hospital accommodation the provision of free hospital service is often an illusory one, patients may have to wait months before being admitted. The scheme has led to a greater use of private hospitals and nursing homes, and the position of many small inefficient hospitals has been confirmed. Private hospital fees have risen in consequence.

Up to the present the scheme has shown too many defects to be regarded as an ideal basis for a general medical practice for the community, but it is possible that in time a more progressive and constructive scheme may be evolved out of that at present in operation.

Exemption for Students

In order to ensure a steady flow of trained professional men to meet the requirements of the services and the increased demands of the postwar period, action has been taken by the manpower authorities to exempt certain classes of students from call ups for compulsory military service. The director general of manpower has announced that all full time students accepted by a university in the faculties of medicine, science (including pharmacy), engineering, dentistry, agricultural science and veterinary science are totally reserved. As far as the medical profession is concerned, it is of paramount importance that there should be sufficient numbers of trained personnel to meet the increased demands which the proposed national health services must necessarily place on the profession. There must, however, be a limitation and control of the number of admissions to the reserved faculties to guard against an unwarranted influx of students seeking to avoid military service. A workable plan must be devised for securing the best material and allocating it to the best advantage.

Marriages

THOMAS MICHAEL HUGHES, Columbus, Ohio, to Miss Dorothy Ramona Abegglen of Tekoa, Wash., in San Diego, Calif., June 15.

WILLIAM EDWARD BALDWIN JR, Dunn, N C, to Miss Martha Virginia Dixon of Pisgah Forest, July 2.

HENRY B DIVERTY, Woodbury, N J, to Miss Jeanette Lee Livingston of Middletown, N Y, July 9.

ROBERT WILSON KING to Miss Dorothy Williamson Sisk, both of Fayetteville, N C, July 13.

THOMAS P WARING JR, Savannah, Ga, to Dr RUTH MOYER of Baraga, Mich, July 11.

CHARLES M HARRIS JR to Miss Margaret Ann Holland both of Atlanta, Ga, July 3.

JOHN SHEDD SCHWEPPE, Lake Forest, Ill, to Miss Lydia H Elliott of Winnetka, July 17.

IRWIN M MARCUS to Miss Phyllis Harriet Pincus, both of Chicago, June 23.

JOHN R U CAMIBELLI, Gilroy, Calif, to Mr. Ka, Christ recently.

Deaths

Arthur Thomas McCormack, widely known as secretary of the Kentucky State Board of Health and president of the American Public Health Association in 1937, died in Louisville August 7, aged 70, of coronary sclerosis. His death brought to an end a career of more than forty-five years in public medical service. Dr. McCormack was born in Nelson County, Ky., Aug. 21, 1872. He was the son of Dr. Joseph Nathaniel McCormack, renowned as one of the most important leaders in the reorganization and building of the American Medical Association. Following graduation from Ogden College at Bowling Green, Ky., where he received the B.A. degree in 1892, he attended the College of Physicians and Surgeons of Columbia University and received his M.D. degree in 1896. He then returned to Kentucky, opened an office in Bowling Green in 1897 and soon thereafter was named health officer of Warren County. He became assistant state health officer in 1898 and held that position until 1912 when he became state health commissioner.

In 1900 Dr. McCormack became surgeon general of the Kentucky National Guard and held that position until 1908. In 1911 he accepted a commission as lieutenant in the Medical Reserve Corps. With the beginning of World War I in 1917 he was appointed major and organized Base Hospital No. 59. He was about to proceed overseas with the base hospital when he was ordered to the Panama Canal Zone by General Gorgas, succeeding General Gorgas as chief health officer and completing the building of the Ancon Hospital. In this position he held the rank of lieutenant colonel. An interesting feature of that service was his control of an epidemic of cerebrospinal meningitis on the Japanese S. S. *Anjo Maru*. For this he received the special thanks of the mikado. He was a member of the Association of Military Surgeons and secretary and president of the Medical Veterans of the World War.

In all work in the field of public health in America Dr. McCormack was prominent. His death concluded more than thirty years as secretary of the Kentucky State Board of Health. He had been president of the American Public Health Association in 1937, special consultant of the U. S. Public Health Service, and organizer and dean of the School of Public Health of Kentucky. He had been president of the Conference of State and Provincial Health Authorities of North America and he was a member of the National Tuberculosis Association, Gorgas Memorial Institute and the National Health Council. His most important recent activity was the presentation of a report on the establishment of full time county health departments, published in *THE JOURNAL*. In his public life Dr. McCormack had been president of the Kentucky Conference on Social Work and he was state flood director for the flood which menaced Kentucky in 1937.

In the field of organized medicine Dr. McCormack was prominent as secretary of the Kentucky State Medical Association for many years. He founded the *Kentucky Medical Journal* in 1901 and was subsequently director and editor. He was a fellow of the American College of Surgeons and of the American Medical Association. He served in the House of Delegates from 1908 to 1914, 1916-1917, 1919 to 1931, in 1933 and again from 1937 to 1943 inclusive. During these years he gave of his time and thought on many occasions to the many reference committees to which he was assigned and in which he was especially efficient because of his many years of service. He was president elect of the Southern Medical Association in 1939 and president in 1940. During recent years he had spent much time in Washington acting in an advisory capacity to

several government agencies. For his work in the field of public health and education he was honored with the M.A. from Bethel College at Russellville, Ky., in 1900, the degree of Dr. P.H. from Detroit College of Medicine and Surgery in 1925, the degree of D.Sc. from Berea (Ky.) College in 1926, and LL.D. from Transylvania University in 1930. The literary contributions of Dr. McCormack included many editorials and articles for the journal which he edited. He wrote also a book entitled "Course in Physical Education for the Common Schools of Kentucky," published in 1920. His hereditary statesmanship, idealism and devotion to the public good and to public service made Dr. McCormack a notable figure in American medicine.

Charles Macfie Campbell, noted psychiatrist, died at Wyman House, Cambridge, Mass., August 7 of heart disease, aged 66.

Born in Edinburgh, Scotland, Sept. 8, 1876, Dr. Campbell studied at George Watson's College receiving the M.A. at Edinburgh University in 1897, the M.B. and Ch.B. in 1902 and the degree of doctor of medicine in 1911. He came to the United States in 1904 and became a citizen in 1918. For a time he was assistant physician at the Psychiatric Institute at Ward's

Island, New York, and at Bloomingdale Hospital, White Plains. In 1913, following several years as instructor in psychopathology at Cornell University Medical College, Dr. Campbell went to Johns Hopkins University School of Medicine to become associate professor of psychiatry and associate psychiatrist at the Johns Hopkins Hospital and to serve under the direction of Adolf Meyer in the newly opened Phipps Psychiatric Institute. In 1920 he joined the Harvard Medical School as professor of psychiatry, later assuming the position of medical director of the Boston Psychopathic Hospital.

Dr. Campbell was a sponsor of the early movement to establish an organized program of mental hygiene in this country. Long identified with the National Committee for Mental Hygiene, he was in 1931 named one of a group to serve as an advisory board to its new division of psychiatric education. In 1932 he returned to his native land to participate in the one hundredth anniversary of the British Medical Association.

Dr. Campbell served as president and vice president of the American Board of Psychiatry and Neurology, Inc. and president of the American Psychiatric Association, Massachusetts Society for Mental Hygiene and Massachusetts Psychiatric Society. He was a member of the Association for Research in Nervous and Mental Disease, once

serving as vice president the American Neurological Association, New England Society of Psychiatry, American Psychopathological Association, American School Hygiene Association, British Medical Association, Royal Medico-Psychological Association of Great Britain and Ireland and the Royal Society of Medicine of England. He delivered such notable lectures as the Thomas W. Salmon Memorial Gehrman Pasture and Lowell lectures. In addition to numerous articles, Dr. Campbell was the author of *Destiny and Disease in Mental Disorders*, *Delusion and Belief*, *Focal Symptoms in General Paralysis*, *Human Personality and the Environment*, *A Present-Day Conception of Mental Disorders* and *Towards Mental Health*. The Schizophrenic Problem.

William Henry Humiston, Vero Beach, Fla., Long Island College Hospital, Brooklyn, 1879, member of the House of Delegates of the American Medical Association in 1902, member and past president of the Ohio State Medical Association, past president of the Cleveland Medical Society and the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, clinical professor emeritus of gynecology at the Western Reserve University School of Medicine for six years, a member of the board of health of Cleveland, a member of the original Troop A 107th Cavalry of the Ohio National

ARTHUR THOMAS MCCORMACK, M.D., 1872-1943

Guard, during World War I served as a member of the district board of appeals, formerly a director of the Cleveland Chamber of Commerce, formerly gynecologist on the staff of the City Hospital, Cleveland, for many years on the staff of St. Vincent Charity Hospital, Cleveland, where he died June 15, of myocarditis, aged 87.

Bert Raymond Hoobler, Detroit, Cornell University Medical College, New York, 1905, member of the Michigan State Medical Society and the American Pediatric Society, emeritus professor of pediatrics at the Wayne University College of Medicine, where he had been professor and head of the department from 1914 to 1936, at one time on the staff of the Bellevue Hospital, New York, organizer and medical superintendent of the Hoobler Convalescent Hospital and Rest Home, served as chief of the medical staff of the Children's Hospital, a member of the staffs of the Woman's Hospital, Harper Hospital, Florence Crittenton Hospital, William Booth Memorial Hospital, Receiving Hospital and the Harper Hospital, where he died, June 11, of coronary thrombosis, aged 71.

Walter Douglas Bishop, Kansas City, Kan., Atlanta Medical College, 1915, member of the Kansas Medical Society, for five years Wyandotte county physician, served during World War I, member of the staffs of the Providence, Bethany and St. Margaret's hospitals, aged 56, died, May 21, of coronary occlusion.

Wilbur Howard Bliss, Northboro, Mass., Long Island College Hospital, Brooklyn, 1889, aged 84, died, April 25, of carcinoma of the prostate.

Otis J. Bryan @ Pecos, Texas, Memphis (Tenn.) Hospital Medical College, 1902, past president and secretary of the Reeves-Ward-Winkler-Pecos Counties Medical Society, chairman of the Selective Service Board for Reeves County during World War I and recently, for fifteen years served as health officer of Reeves County, member of the school board, aged 63, died, April 28.

Louis Leonard Corcoran @ Rock Rapids, Iowa, Northwestern University Medical School, Chicago, 1907, aged 66, died, May 18.

Frank Eastman, Atlanta, Ga., Hahnemann Medical College of Philadelphia, 1877, aged 87, died, June 8, in St. Joseph's Infirmary of chronic myocarditis.

Hans Edward Eiel @ Buffalo Center, Iowa, Keokuk (Iowa) Medical College, 1899, past president and secretary of the Hancock-Winnebago Counties Medical Society, formerly health officer, postmaster of Buffalo Center, aged 67, died, May 29, in the Dolmage Hospital of coronary thrombosis.

Erle D. Forrest, Cranston, R. I., Tufts College Medical School, Boston, 1912, aged 54, died, May 25, in the Jane Brown Memorial Hospital, Providence, of hypertensive cardiovascular disease.

William H. Gohlman, Van Nuys, Calif., Medical Department of Tulane University of Louisiana, New Orleans, 1896, aged 69, died, May 17, of cerebral hemorrhage and hypertension.

John C. Gourley @ Windber, Pa., Western Pennsylvania Medical College, Pittsburgh, 1904, a member of the board of education of Windber from 1924 to 1930, roentgenologist and obstetrician to the Windber Hospital, aged 68, died, May 16, of cerebral arteriosclerosis.

Edward Benjamin Gray, Cincinnati, Howard University College of Medicine, Washington, D. C., 1913, served during World War I, aged 55, died, May 27, in the Jewish Hospital.

John Louis Gray @ Anderson, S. C., Bellevue Hospital Medical College, New York, 1895, served on the staff of the Anderson County Hospital, aged 74, died, May 19, of heart disease.

Ernest Nelson Greenman @ Kankakee, Ill., Jefferson Medical College of Philadelphia, 1912, served during World War I, aged 56, died May 31, of heart disease.

Ezra Clarence Grim @ Kirksville, Mo., Washington University School of Medicine, St. Louis, 1901, an Affiliate Fellow of the American Medical Association, the founder and formerly superintendent of the Grim-Smith Hospital and Clinic, aged 69, died, May 26, of uremia.

Augustus G. Haerther, Chicago, Chicago Medical College, 1883, aged 88, died, May 30, of intestinal obstruction and carcinoma of the hepatic flexure of the colon.

George P. Hale, Memphis, Mich., the Hahnemann Medical College and Hospital, Chicago, 1887, for many years health officer, aged 86, died, May 21, of heart disease.

William Wilson Hale, Cheyenne, Wyo., College of Physicians and Surgeons, Keokuk, Iowa, 1877, at one time

professor of therapeutics at the Drake University College of Medicine, Des Moines, aged 91, died, May 24, in the Memorial Hospital of Laramie County of chronic glomerulonephritis.

John Mead Hall @ New York, Cornell University Medical College, New York, 1904, formerly deputy health officer of the Port of New York, served in the medical corps of the U. S. Army during World War I, on the staff of the New York Eye and Ear Infirmary as senior assistant surgeon until February 1943, when he retired as an honorary surgeon, aged 62, died, June 7, in the New York Hospital of heart block.

Guido B. Hammond, English, Ind., Kentucky School of Medicine, Louisville, 1903, member of the Indiana State Medical Association, for many years president of the school board, president of the English State Bank and the Crawford County Security Company, aged 67, died, June 7, in the Kentucky Baptist Hospital, Louisville, of hemorrhage following a gastroenterostomy.

Robert Thomas Hawks, Carson, Va., Medical College of Virginia, Richmond, 1907, chairman of the school board and coroner of Prince George County for many years, medical examiner for the Prince George Selective Service Board, a director of the Bank of Southside Virginia, aged 60, died, June 8, of angina pectoris.

William F. Hilger, Milwaukee, Milwaukee Medical College, 1903, also a pharmacist, aged 69, died, May 22, in St. Anthony Hospital of coronary occlusion.

Emma Linton Hill @ Oswego, Kan., Kansas Medical College, Topeka, 1895, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902, aged 84, died, May 14, in the Mercy Hospital, Parsons, of injuries received in an automobile accident.

L. L. Hines, Richland Center, Wis., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1909, on the staff of the Richland Hospital, aged 71, died, May 21, of nephritis.

Francis Victor Hoehn @ Buffalo, University of Buffalo School of Medicine, 1910, served as a captain in the medical corps of the U. S. Army in France during World War I, a member and vice president of the medical staff of the Charity Eye, Ear and Throat Hospital of Erie County, consulting rhinolaryngologist to the Edward J. Meyer Memorial Hospital, member of the staffs of St. Mary's Infant Asylum and Maternity Hospital and the Emergency Hospital of the Sisters of Charity, where he died, June 1, of ischio-rectal abscess, aged 64.

Jacob J. Hood @ Cicero, Ill., Jenner Medical College, Chicago, 1902, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903, for seven years health commissioner of Cicero, one of the founders and directors of the Cicero State Bank, on the staff of the Garfield Hospital, Chicago, aged 73, died, May 27, of intestinal obstruction.

Frank Ignatius Horn, Los Angeles, Magyar Kiralyi Pazmany Petrus Tudomanyegyetem Orvosi Fakultasa, Budapest, Hungary, 1894, member of the California Medical Association, aged 73, on the visiting staff of the Cedars of Lebanon Hospital, where he died in May of hypertrophy of the prostate and septicemia.

Edward Hougén @ Wisconsin Rapids, Wis., Northwestern University Medical School, Chicago, 1897, aged 72, died, June 21, in the Memorial Hospital, Sheboygan, of epithelioma of the tongue.

John Blanch Howell @ Canton, Miss., Vanderbilt University School of Medicine, Nashville, Tenn., 1905, president of the Central Medical Society in 1933, member of the Mississippi State Board of Health from 1936 to 1942, chief surgeon on the staff of the Kings Daughters Hospital, surgeon for the Illinois Central Railroad, formerly a captain of the Mississippi National Guard, physician-surgeon for the Pearl River Lumber Company, past president of the Rotary Club, aged 62, died, May 24, of coronary occlusion.

Francis Eugene Hubbard, Eau Claire, Mich., Michigan College of Medicine and Surgery, Detroit, 1902, for many years a druggist, served several terms on the school board, aged 77, died, June 17, of carcinoma.

Percy Hudson, Utica, Miss., Louisville (Ky.) Medical College, 1906, member of the Mississippi State Medical Association, aged 60, died, May 27, of heart disease.

Julius Kershaw Huff, Hodges, S. C., Jefferson Medical College of Philadelphia, 1894, aged 70, died, June 6, of malignant tumor of the esophagus.

Alonzo Homer Kuntabrew, Springfield, Ill., Meharry Medical College, Nashville, Tenn., 1897, aged 68, died, May 20, in St. John's Hospital of hypertensive heart disease and bronchopneumonia

Allan Napier Kerr, Pacific Palisades, Calif., Wisconsin College of Physicians and Surgeons, Milwaukee, 1903, member of the Washington State Medical Association, for many years on the staffs of various Veterans Administration facilities, aged 68, died, May 6, in the Veterans Administration Facility, West Los Angeles, of granuloma of the septum and pulmonary edema

Edward R. Layne, Whittier, Calif., Arkansas Industrial University Medical Department, Little Rock, 1888, aged 80, died, May 25, of coronary thrombosis and arteriosclerosis

Arthur Jack Leader, Poughkeepsie, N. Y., Syracuse University College of Medicine, 1930, member of the Medical Society of the State of New York and the American Psychiatric Association, senior assistant physician to the Hudson River State Hospital, aged 55, died, May 31, of carcinoma-tosis and mediastinal chondromyxosarcoma

Max David Mayer of New York, Columbia University College of Physicians and Surgeons, New York 1915, specialist certified by the American Board of Obstetrics and Gynecology, Inc., member of the American Psychoanalytic Association, fellow of the American College of Surgeons on the staffs of Mount Sinai and Sydenham hospitals and New York Home for Aged and Infirm Hebrews, aged 50, died, May 28, of leukemia

William C. McCammon, Knoxville, Tenn., Tennessee Medical College, Knoxville, 1899, aged 71, died, June 3, of carcinoma of the stomach

Henry C. McQuillin, Madison, Wis., Physio-Medical College of Indiana, Indianapolis, 1897, aged 70, died, May 25, of hypertensive cardiovascular renal disease

Nelson Merrill of Marshalltown, Iowa, State University of Iowa College of Medicine, Iowa City, 1893, served one term as a member of the Marshalltown independent school district, on the staffs of the Evangelical Deaconess Home and Hospital and St. Thomas Mercy Hospital, aged 80, died, May 21, of angina pectoris

Charles S. Newlon of Kansas City, Mo., College of Physicians and Surgeons, Keokuk, Iowa, 1881, an Affiliate Fellow of the American Medical Association, at one time superintendent of the School for Feeble-Minded Youth, Winfield, Kan., aged 85, died, June 4, of carcinoma of the liver

William Boyd Nicholl, Oakland, Calif., Colorado School of Medicine, Boulder, 1901, aged 69, died, April 8, of coronary thrombosis and hypertension

Sofie Amalia Nordhoff-Jung of Washington, D. C., Columbian University Medical Department Washington 1893, professor of gynecology emerita at the Georgetown University School of Medicine, in 1923 established the Sofie A. Nordhoff-Jung Cancer Research Prize to encourage researches in the etiology, prevention and treatment of cancer, in 1927 received a medal from the German government for distinguished services in Red Cross work rendered in Germany before the United States entered World War I, aged 76, died, June 6

John Eugene Osborne, Rawlins, Wyo., University of Vermont College of Medicine, Burlington, 1880, formerly governor of the state of Wyoming and mayor of Rawlins, in 1896 elected representative to Congress, at one time first assistant secretary of state, chairman of the board of directors and for many years president of the Rawlins National Bank, aged 89, died, April 24, of chronic myocarditis

Eleanor Parry of Huntington, N. Y., Woman's Medical College of the New York Infirmary for Women and Children, New York 1894, aged 82, died, May 22, in the New York Infirmary for Women and Children, New York

Felix Peebles, Jefferson, Texas, Gate City Medical College, Texarkana, Ark., 1905, St. Louis College of Physicians and Surgeons 1913, member of the State Medical Association of Texas, past president and secretary of the Cass Marion

Counties Medical Society, examiner for the Selective Service of Marion County, aged 63, died, April 5, of cerebral hemorrhage and myocarditis

Robert Sheild Perkins, Norfolk, Va., Hahnemann Medical College of Philadelphia, 1872, aged 95, died, June 4, of heart disease

Henry Lincoln Plummer, Boston, Harvard Medical School Boston, 1890, aged 75, died, May 25, in the Boston City Hospital

Jacob H. Polozker, Detroit, Detroit College of Medicine, 1910, served on the staff of the Children's Hospital, aged 55, died, May 15, of coronary thrombosis

William Fletcher Priestley, Oakland, Calif., Cooper Medical College San Francisco, 1912, member of the California Medical Association, served during World War I, at one time health officer of San Joaquin County, aged 58, died, May 29, of coronary thrombosis

James Pullman of Brooklyn, Yale University School of Medicine New Haven, Conn., 1899, formerly clinical professor of medicine at the Long Island College of Medicine, served on the staffs of the Kings County, Lutheran and Swedish hospitals, aged 68, died, May 28, of arteriosclerotic heart disease

Samuel Henry Watters, Iowa City, Iowa, University of the City of New York Medical Department, 1884, aged 91, died, May 30, of senility

William R. Wellborn, Elkin, N. C., North Carolina Medical College Davidson, 1905, a member of the staff of Hugh Chatham Memorial Hospital, aged 60, died suddenly, May 24, of coronary occlusion

Edward Hayward Wells of New York, Bellevue Hospital Medical College, New York, 1895, aged 77, died, May 18, of angina pectoris

James S. Wheeler, Greer, S. C., University of Nashville (Tenn.) Medical Department 1902, formerly a member of the U. S. Public Health Service Reserve, veteran of the Spanish-American War and World War I, aged 70, died, May 28, in the Greenville (S. C.) General Hospital

Warren Everett White, Spokane, Wash., Kansas City (Mo.) Medical College 1902, aged 69, died, May 25, of cardiovascular renal disease

Samuel Sherman Widener, Ponder, Okla., Chattanooga (Tenn.) Medical College 1903, veteran of the Spanish-American War, aged 68, died, May 8, of cerebral hemorrhage

James Griffin Wilbanks, Amarillo, Texas, Birmingham (Ala.) Medical College, 1912, member of the State Medical Association of Texas, on the staffs of the Northwest Texas Hospital and St. Anthony's Hospital, aged 60, died, May 27, of coronary thrombosis

Thomas Robert Waters Wilson of Greenville, S. C., Baltimore Medical College 1897, past president and secretary of the Greenville County Medical Society, served in the medical corps of the U. S. Army during World War I, aged 68, for twenty-eight years pathologist at the Greenville General Hospital, where he died, May 3, of cerebral arteriosclerosis and left hemiplegia

Isaac Henry Wineberg of Quincy, Ill., Chicago Medical School 1927, served on the staffs of St. Mary and Blessing hospitals, aged 54, died, May 12, of coronary occlusion

Abraham Samuel Wingersky, Boston (licensed in Massachusetts in 1898), aged 67, died in May

KILLED IN ACTION

Simon Warmenhoven, Grand Rapids, Mich., Marquette University School of Medicine Milwaukee 1939, began active duty in October 1940 as a captain in the medical corps of the U. S. Army (National Guard) attached to the 120th Infantry Medical Detachment at Camp Livingston, La., and later became a major and lieutenant colonel, aged 33, was killed in action in the Southwest Pacific, May 5

LIEUT. COL. SIMON WARMENHOVEN
1910-1943, M. C., U. S. ARMY

Correspondence

SALT REQUIREMENTS IN HOT CLIMATES

To the Editor—I was attracted by the letter in *THE JOURNAL*, July 24, from the London correspondent in regard to "Salt and Water Requirements in Hot Climates." Take the figures quoted from the Army Medical Department bulletin that in hot countries a man on exercise excretes from 5 to 8 liters of sweat and needs not over 25 Gm salt unless the sweat exceeds 2 gallons (Imperial measure, I presume) or a little over 95 liters. Sweat is hypotonic. Consequently when a liter is excreted there would be but for the kidney a hypertonic condition in the intracellular fluids. The kidney, however, guards the salt concentration zealously and excretes sufficient salt to keep the fluids isotonic. The net result of losing a liter of sweat is that of losing a liter of isotonic solution containing 85 Gm of salt. If a man is to lose but 5 liters of sweat it means he has lost 425 Gm of salt. If this keeps up a man is bound to get out of balance and get miners' cramps. The article states that for hard work more than 9 liters is required, to be supplemented by salt tablets to be taken during meals or rest periods. The tablets are of 10 Gm, taken with a pint of water. It would be more rational to take these at more frequent intervals.

ROBERT J. B. HIRSHARD, M.D., State Sanatorium, Ark.

CHEMOSURGERY AND RADIATION THERAPY IN EXTERNAL CANCER

To the Editor—I do not wish to let go unchallenged the partial misconception held by your editorial writers regarding the relative efficiency of chemosurgery and radiation therapy in the treatment of external cancer. Those of us who have had the opportunity of seeing hundreds of cancers respond to chemosurgery after previous unsuccessful x-ray or radium treatment know that, despite the modern physical perfection of these agents, they can never approach the effectiveness of chemosurgery.

Tumors vary greatly in radiosensitivity, and for this reason a great many do not respond even to the most expert radiation therapy. Moreover, the radiotherapist has no way of knowing the exact extent of a carcinoma except perhaps in its earliest stages. Our reconstructions of carcinomas frequently show small caliber outgrowths which had been completely unsuspected from clinical examination, these can be accurately followed out and eradicated by the chemosurgeon, but the radiotherapist would never know they were there, though he might suspect it when recurrences appeared months or years later.

It is natural that some of those particularly interested in radiation therapy will be loath to admit the value of competing methods, thus Ackerman and Eberhard apparently were not convinced of the superiority of chemosurgery except in certain cancers no longer amenable to radiation or surgery. It is my contention that the microscopic control afforded by chemosurgery is also very advantageous in the treatment of early cancer. Dr. Ackerman visited me after clinic hours for a hurried fifteen minute talk, and it is probable that he did not get a complete insight into all the applications of chemosurgery. I gave him my complete approval in his fight against irregular cancer paste practitioners as long as he didn't confuse the University of Wisconsin's chemosurgery with them. Incidentally, he has since asked me to treat a patient whose cancer did not respond to radiation therapy in his institution.

I only ask that the profession keep an open mind on the subject until I am able to muster the data which will eventually prove the worth of chemosurgery. Unfortunately time is required, so, although the series now amounts to 1,200 cases, those treated three and five years ago are only now reaching satisfactory numbers.

FREDERIC E. MOHS, M.D., Madison, Wis.
Assistant Professor of Chemosurgery, State
of Wisconsin General Hospital

USE OF POWDERED SULFATHIAZOLE IN NOSE AND THROAT

To the Editor—In *THE JOURNAL* of May 15 under Current Comment, page 180, I read of the use of sulfathiazole locally in the nasopharynx and larynx, using a finely powdered spray blown into the nostrils, pharynx and larynx, or using a solution in $\frac{1}{4}$ cup of hot water of a $7\frac{7}{10}$ grain (0.5 Gm) tablet of sulfathiazole as a gargle, as reported by Fenton and Freeman.

For the past two years I have used $7\frac{7}{10}$ grains to 15 grains of sulfathiazole in $\frac{1}{4}$ cup of hot water as a gargle, but, better yet, have both my patients and myself chew a stick of chewing gum and then wrap a $7\frac{7}{10}$ grain tablet of sulfathiazole in the gum mass and chew the mixture and keep it in the mouth as long as possible. The taste is slightly bitter at first but then rapidly becomes sweet. Immediate relief of pain and discomfort in the throat invariably follows.

I have thought of incorporating a tablet of sulfathiazole in flavored hard candy to be used as a lozenge and believe this could be beneficial in throat infections, especially for children.

By means of the chewing gum method, I believe the concentration of sulfathiazole can be maintained in the mouth and pharynx for some time, since the solubility of the drug is constant. It is well known that gargles do not reach the nasopharynx, while swallowed saliva does. I have used this method during the day as frequently as I believed necessary.

It has been interesting and enjoyable to me to be able to read of procedures used by individuals who thought along similar lines at almost the same time as others.

JOSEPH GERTNER, Lieutenant, M.C., A.U.S.

SWELLING OF POPLITEAL BURSÆ IN BRUCELLOSIS

To the Editor—The article by Meyerding and Van Demark on "Posterior Hernia of the Knee" in the July 24 issue of *THE JOURNAL* impels me to call attention to the fact that swelling of popliteal bursae may also be associated with such systemic illnesses as chronic brucellosis.

In this infection, about which too little is known, I have observed six instances of popliteal bursitis of varying size and accompanied by from little to rather considerable discomfort. In all cases but 1 there was either pronounced improvement or disappearance of the bursal involvement when these patients responded clinically and serologically to *Brucella abortus* vaccine treatment. Since none were treated surgically it is impossible to say whether any cases represented true hernia of the synovial lining of the knee joint or whether they were all noncommunicating bursae.

There is no reference in the literature to popliteal bursitis in brucellosis as far as I have been able to determine. I briefly mentioned it in my monograph "Brucellosis (Undulant Fever) Clinical and Subclinical."

HAROLD J. HARRIS, Lieutenant Commander (MC),

MEDICOLEGAL ABSTRACTS

Osteopathic Practice Acts (California) Power of Legislature to Impose Educational Standards in Addition to Those Imposed in the Osteopathic Initiative Act of 1922.—Under the applicable California law between 1913 and 1922 all persons, whether they were nonsectarian practitioners homeopaths, eclectics or osteopaths, desiring licenses to practice the healing art without restriction and possessing the qualifications prescribed by law, were examined and licensed by the board of medical examiners. A separate osteopathic practice act in the form of an initiative measure was adopted by the California electorate in 1922, which created an independent board of osteopathic examiners and gave it jurisdiction, formerly residing in the Board of Medical Examiners, over graduates of osteopathic schools. The initiative measure "was intended to effect administrative changes only and made no substantive changes in the standards of education and examination for the physician and surgeon certificate" [the license to practice without restriction] required under the existing medical practice act. In the words of the court, the initiative made the Medical Practice Act (presumably the educational requirements therein) applicable to graduates of osteopathic schools. Subsequently a so-called business and professions code (a codification of the then existing statutory provisions relating to the licensing of businesses, professions and vocations) was adopted by the legislature and by an amendment to that code enacted in 1941 it was provided that before a previously licensed osteopath could effect an annual registration, which would give him the legal right to practice during the ensuing year, he must, in addition to paying the required annual license fee, present evidence that in the preceding year he had completed a minimum of thirty hours of professional educational work approved by the osteopathic board.

The petitioner a graduate of an osteopathic school, who was issued a physician and surgeon certificate (the license issued permitting the practice of medicine and surgery without restriction) by the osteopathic board in 1934, refused to tender for the issuance of an annual registration certificate for 1943 'evidence of the performance of thirty hours or professional educational work' during 1942. When the osteopathic board refused to issue to him the certificate desired he brought mandamus to the Supreme Court of California to compel the board to do so.

The osteopath contended first that since the osteopathic initiative act adopted in 1922 made the Medical Practice Act [presumably the education requirements contained therein] applicable to graduates of osteopathic schools such rights and duties remain invariable. Apparently the gist of this contention was that since the osteopathic initiative act was adopted by the electorate it could be amended in no particular by the legislature and that since the initiative adopted the educational standards imposed by the then existing medical practice act the provision adopted by the legislature in amending the business and professions code in 1941 requiring osteopaths annually to complete a minimum of thirty hours of professional educational work was an invalid attempt to amend the initiative act of 1922. There is no provision in the osteopathic initiative act answered the Supreme Court limiting the power of the legislature to change the standards for receiving or holding a physician and surgeon certificate. The argument submitted to the voters in 1922 in support of the initiative act set forth that that act left the legislature free to change the standards of education and examination. The initiative act itself demonstrates the care with which its framers guarded that freedom and made the act exclusively administrative in character clearly leaving it to future legislatures as they saw fit to impose additional educational requirements on osteopaths.

The osteopath next contended that the 1941 amendment to the business and professions code violates article I, section 21

of the constitution of California in that, since osteopaths must meet the same educational requirements as other practitioners who are legally entitled to practice medicine and surgery without restriction, they cannot be subjected to requirements in addition to those imposed on the others and that no practitioners other than osteopaths are required to complete thirty hours of professional educational work during any one year. It is generally recognized, however, said the Supreme Court, that the power to regulate the treatment of disease is an elastic one and that regulations may vary according to the schools or methods of practice as long as they entail no unreasonable discrimination, citing *In re Rust*, 181 Cal 73, 183 P 548, which held the California optometry act of 1913, forbidding osteopaths but not nonsectarian physicians from practicing optometry without a license from the state board of optometry, did not violate article I, section 21 of the state constitution. The opinion in that case, continued the court, set forth a history of the distinctions that the legislature has made at various times between practitioners of osteopathy and other practitioners. Thus for many years different licenses were issued to osteopaths than to physicians and surgeons with different rights and duties attached to the respective licenses. Although the certificates as well as the educational requirements for osteopaths and physicians and surgeons may now be the same, the legislature is as free to return to different certificates and educational requirements as it was to abandon them. The petition for writ of mandate was denied—*Gauble v Board of Osteopathic Examiners of California*, 130 P (2d) 382 (Calif, 1942).

Charitable Hospitals Liability for Failure to Furnish Proper Equipment—Mrs. Canney was received about 9 30 p m, Nov 7, 1940, as a pry patient in the Providence hospital, a charitable institution, to be delivered of child. A cesarean section was performed on her about an hour later, after which she was given a blood transfusion and taken to her room about 11 50 p m. She was placed in a bed previously heated with an electric pad which had been removed. The patient was left in charge of a special nurse, obtained for the patient by the hospital at her husband's request, and this nurse was alone with the patient from 1 to 7 a m. About 5 or 6 a m when the nurse bathed the patient it was discovered that both heels were burned. What heating appliances, if any, had been placed in the bed by the special nurse between midnight and that time are not shown, since the nurse was not called as a witness in the litigation that subsequently ensued. Later the patient and her husband brought suit against the hospital, alleging that the patient's injuries

were the sole, direct and proximate result of the administrative negligence of the defendants, which consisted solely of the failure of defendants to furnish proper equipment for the purpose of warming the feet of plaintiff under a regulated heat so that the said application of the said instrument would not result in injury.

From a judgment in favor of the plaintiffs, rendered on a verdict of the jury, the hospital appealed to the Supreme Court of Washington.

The defendant hospital, said the Supreme Court, being a charitable hospital, is not liable for the negligent act of an employee, unless it is established that the hospital failed to exercise ordinary care in the selection or retention of the negligent employee. The fact that compensation is exacted for services rendered does not, of itself, deprive an institution of its charitable status. It is generally held that, since a special nurse is the agent of the patient and is not an employee of the hospital and not subject to its control, the acts of the special nurse do not create liability on the part of the hospital. The plaintiffs invoke the rule enunciated in *Miller v Sisters of St Francis*, 5 Wash (2d) 204, 105 P (2d) 32, that a hospital, even if it is a charitable institution, will be required to respond in damages for injuries proximately resulting from failure to furnish proper equipment, which failure apparently would constitute "what is called administrative negligence as distinct from failure to exercise due care in the selection of proper physicians and nurses." That rule, however, continued the court, is subject to the quali-

fication that if the article which it is the duty of the hospital to supply is obviously unfit for the use for which it was intended, and a special nurse in charge of a patient uses it in violation of the standards of care of nursing practice, the hospital cannot be chargeable with any injurious effects therefrom but the rule is otherwise if the defect is not patent. See *Payne v Santa Barbara Cottage Hospital*, 2 Cal App (2d) 270, 37 P (2d) 1061 and *Ratliffe v Wesley Hospital*, 135 Kan 306, 10 P (2d) 859. If we apply the law to the facts of this case, it is clear that the trial court was not warranted in submitting the cause to the jury for its determination as to the negligence of the hospital. From midnight, when she was returned from the operating room to her private room, until 7 a m, the patient was in charge of a special nurse who had been employed at the request of her husband. The special nurse was not called as a witness. What heating appliances, if any, she placed in the patient's bed during the period she was in charge of the patient are not known. There is an absence of evidence of any lack of care on the part of the hospital in providing competent servants. There is no evidence that the hospital failed to furnish proper appliances. The mother of the patient testified that between 9 30 and 10 a m, about five hours subsequent to the time it was discovered that the patient had burns on her feet, she called to see the patient and saw an ordinary rubber hot water bottle which, although it was not hot then, was at the patient's feet. She testified that she could not tell whether there was any cover on the hot water bottle. On the other hand, evidence was adduced on behalf of the hospital that the hot water bottles supplied by it are standard equipment used in all hospitals, that covers are supplied for the hot water bottles, which are never used without a cover, and that a hot water bottle is always placed between the blankets and never next to the patient. If, said the court, the special nurse placed an uncovered hot water bottle to the feet of the patient, that failure of the special nurse in not having the bottle covered or in protecting it by blankets is not administrative negligence on the part of the hospital. If the hot water bottle supplied by the hospital was obviously unfit for the use for which it was intended—and there is no showing to that effect in the record—and if the special nurse who was employed by and was the agent of the patient and her husband used it in violation of the usual standards of nursing practice, the hospital cannot be charged with the resultant injurious effects on the patient.

The judgment in favor of the patient and her husband was accordingly reversed and the cause remanded with direction to dismiss the action—*Canney v Sisters of Charity of House of Providence*, 130 P (2d) 899 (Wash, 1942).

- Wisconsin, State Medical Society of Milwaukee, Sept 13-15. Mr Charles H. Crownhart, 110 East Main St., Madison, Secretary.

Current Medical Literature

AMERICAN

The American Library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1922 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Familial Blood Studies in Mediterranean Anemia.—In sixteen families with Mediterranean anemia 63 persons were examined by Smith and 54 showed abnormalities of the blood. Twelve, all children, were severely anemic and 42, including parents and siblings, had the mild type of this condition. In every one of the sixteen families definite blood changes occurred in at least one parent, and in one family changes were noted in three generations. While all siblings and parents of patients with Mediterranean anemia were examined clinically, hematologically and roentgenographically the recognition of the mild type depended solely on a careful study of the blood. These changes consisted of varying degrees of hypochromic anemia, occasionally polycythemia, an elevated icteric index, the presence of target cells, reticulocytes, macrocytes and stippled red cells and increased resistance of the red cells to hemolysis. The most common findings were anisocytosis and poikilocytosis, basophilic stippling and increased resistance to hypotonic sodium chloride solution. Hypochromic and polychromatophilic macrocytes constituted an important diagnostic feature and were frequently found in predominantly microcytic blood smears. Target cells were not a constant accompaniment in all cases, and they appeared in only half of the patients with mild forms of the disease. Thinness and flatness of the cells may represent the fundamental structural defect of the erythrocytes in Mediterranean anemia. Persons with the mild form of the disease were without symptoms and appeared in perfect health, and the condition could have escaped detection without careful scrutiny of the blood. The degree of skeletal change was usually correlated with the severity of the anemia. The later in childhood the disease became manifest, the less severe was the osteoporosis. In every family with a severely anemic child both parents showed abnormalities of the blood but this cannot be regarded as a universal rule. The children of a parent with the trait run the risk of inheriting the disease in any of its clinical forms from the mildest to the most severe. Since the

disease appears to be transmitted directly from parent to child, the implications of the existence of mild forms of Mediterranean anemia are obvious in communities with large Italian and Greek populations. The pedigrees included in this study suggest that Mediterranean anemia is transmitted as a dominant characteristic. Certain features of the blood in Mediterranean anemia resemble those of sickle cell anemia and to a more limited degree those of hemolytic jaundice.

Sulfadiazine in Treatment of Children.—Winters and Janney reviewed hospital records of 90 patients treated with sulfadiazine. The patients varied in age from 3 weeks to 15 years. Conditions treated included infections of the throat, empyema, septicemia, chronic recurrent pyelitis, peritonitis, abscess, osteomyelitis and meningitis. High blood levels apparently are easily reached and maintained with sulfadiazine because of relatively slow excretion, because of this sulfadiazine may be given at greater intervals or in smaller doses. The drug given to children in doses of $\frac{1}{4}$ to 1 gram per pound in twenty-four hours will produce an average blood level of 7 to 10 mg per hundred cubic centimeters, which is adequate for usual infections. Sulfadiazine is effective against most of the common bacteria producing specific infections, especially against hemolytic streptococci, pneumococci, Staphylococcus aureus, hemolyticus, meningococci and Hemophilus influenzae. Sulfadiazine passes readily into the spinal fluid. Spinal fluid levels can usually be expected to be two thirds or more of the blood level. With high blood levels or poor intake of fluids, the most common reactions are crystals in the urine, red blood cells in the urine, leukopenia and neutropenia. These signs clear up when the administration of the drug is stopped. Sulfadiazine spray for burns produces a satisfactory eschar and is effective in preventing secondary infection. Patients receiving sulfadiazine should be observed with the same care that is advisable after administration of any other sulfonamide compound and the urine and the blood count should be checked regularly.

Omphalocele with Congenital Obstruction.—Omphalocele, or exocoelom, is a true congenital umbilical hernia containing intestine or abdominal organs. This condition is said to occur once in 5,000 to 6,000 newborn infants. The presence of Meckel's diverticulum in an omphalocele has been reported only twice in the English literature. Neville reports a case in which the intestines could not be reduced until the infant was anesthetized. The size of the omphalocele increased from that of a lemon (approximately 6 cm in diameter) to that of a medium sized grapefruit (approximately 12 cm in diameter) within five minutes after birth. This occurred through the swallowing of air when the infant began to cry. The intestines became distended, and this hindered reduction. The infant was operated on when 80 minutes of age. Convalescence was uneventful and at the age of 14 weeks she weighed 12 pounds 11 ounces (5,755 Gm) and appeared perfectly normal. Roentgen examination at the age of 5 months failed to reveal the presence of Meckel's diverticulum. This is probably due to the fact that the diverticulum atrophied after the operation.

Staphylococcal Infections of Skin—According to Goodman, 105 patients with various types of staphylococcal (including 46 with pustular acne) were treated with a combined toxoid-vaccine antigen. Injections were given in increasing doses every fourth day until the tenth dose, of 1 cc. In the usually refractory types of infection, such as pustular acne, treatments were continued in 1 cc doses with the object of achieving desensitization. By means of this desensitizing regimen it appeared that most of the patients were benefited and a great number obtained what may be justifiably considered a clinical cure. The results of this study are promising and warrant the trial of combined staphylococcus toxoid and vaccine as an adjunct in the treatment of some of the ordinarily stubborn staphylococcal dermatoses.

 Multiple Primary Malignant Tumors F P McNamara—p 264

Massive Arsenotherapy in Early Syphilis—The intensive five day intravenous drip method was used by Harris and Sorensen in 41 cases of early syphilis between July 1940 and July 1942. There were 8 cases of seronegative primary syphilis, 8 of seropositive primary syphilis, 23 of secondary syphilis and 2 of early, latent syphilis. Darkfield examinations were positive in 27. Treatment was started as early as possible. The patients received treatment for five days and were observed for two to three additional days before being discharged from the hospital. Each patient was given 240 mg of mapharsen in 2,000 cc of 5 per cent dextrose in isotonic solution of sodium chloride over an eight to twelve hour period daily for five consecutive days. There were no severe reactions such as generalized exfoliative dermatitis or hemorrhagic encephalitis. Twenty-one patients had a primary fever, 10 a secondary fever, and 2 a toxicodermic rash. There were no blood dyscrasias, no instances of renal or liver damage and no fatalities. Thirty six patients experienced arm pain and 24 had nausea and

venting at some time during treatment. In order to evaluate this treatment properly the patients must be followed for at least five years. Of the 41 patients reviewed here 32 have been followed from six to eighteen months with 75 per cent satisfactory results, 18.8 per cent pending and 6.3 per cent failures. The patients with seronegative primary syphilis reached a negative status rapidly. Those with seropositive primary syphilis showed more rapid serologic reversals than did those with secondary syphilis. Only 2 of the 41 patients treated had a proved serologic relapse and were retreated by the same method. One of these patients also had an infectious relapse. One patient with probable reinfection was retreated. One patient out of 33 had a positive spinal fluid after completion of treatment. Two weeks later the spinal fluid was normal. Two women were treated during pregnancy without adverse results. This method of treatment has a public health value.

Calcium and Phosphorus Metabolism and Effects of Dihydroxycholesterol in Renal Osteodystrophy—Liu and Chu report metabolic observations on 5 Chinese patients with various grades of skeletal decalcification with or without other osseous changes occurring in association with moderate to advanced renal insufficiency. The authors apply to this condition the term renal osteodystrophy pointing out that the term renal rickets "though used extensively is objectionable because it identifies the disease of the skeleton with rickets which it is not in many cases although the radiologic appearance and the gross deformities of the bones resemble those seen in rickets. The term renal dwarfism emphasizes only one feature of the disease which is not present in many cases. Objection to the term renal infantilism may be made on the same basis. The term renal osteodystrophy seems to be a suitable generic name to include cases of osseous disorder associated with renal insufficiency, while the exact nature of the pathologic process in the skeleton is still undetermined. The bone lesions of the 5 patients varied from slight or moderate osteoporosis with no

determinates to pronounced rickets with gross deformities. In 2 cases rickets-like changes were present in the epiphyses. The renal insufficiency was moderate in 1 case and far advanced in the rest. In advanced renal insufficiency difficulty in renal excretion of phosphate was evidenced by a small percentage of urinary phosphorus and by hyperphosphatemia. Such evidence could be brought out more clearly by increasing the phosphorus intake. Calcium balance was negative on low or moderate calcium intake and slightly positive on high calcium intake. High fecal excretion of phosphorus after increased phosphorus intake was usually followed by calcium loss even on high calcium intake. Chronic acidosis was present in all the cases. Alkali administration alleviated the acidosis with improvement of renal function and favorable effect on the calcium metabolism. There was no response to ordinary therapeutic doses of vitamin D and it was meager even to massive doses. In contrast to vitamin D, dihydroxycholesterol was remarkably effective in promoting calcium and phosphorus absorption and their deposition in the skeletal store. Iron was efficacious in relieving hyperphosphatemia and in sparing calcium in the intestinal elimination of phosphorus. The lack of response to vitamin D was thought to suggest the possibility of inactivation of vitamin D as a result of functional impairment of the kidney. This was considered to be of primary importance in the genesis of bone disease. A shift of phosphate excretion from the kidneys to the intestine and definite acidosis, present only in advanced renal insufficiency were important aggravating factors. For treatment a low phosphorus, low protein and high calcium diet, alkali, dihydroxycholesterol and iron were indicated. The results with dihydroxycholesterol were particularly favorable.

Trachoma Treated with Sulfanilamide—Gallaher submits a statistical analysis of 318 cases of trachoma most of which were treated by him in the course of the last four years. One hundred and eighty-eight of the patients were males and 130 were females, 209 were white, 108 were Indians and 1 was a Negro. Trachoma is rare among the colored population. All except 3 of the patients received ambulatory treatment. The adults numbered 134, the children 184. The author abandoned the use of copper sulfate sticks because of the pain associated with their use. If a treatment is too painful the patients refuse to return. Silver nitrate was used only in case of complication with gonorrheal infections. It was not usually repeated. One or more of the following therapeutic methods were used in all cases. Sulfanilamide by mouth was used in 199 cases, grating in 26, brosse in 2, zinc sulfate in 58, copper sulfate solution in 46, sulfanilamide (1 per cent in isotonic solution or three chlorides) in 40, sulfathiazole in a 3 per cent ointment in 9 cases, vitamin A (25,000 units or more daily) in 4 cases. The results of sulfanilamide therapy were such that the drug must be included in the treatment of trachoma. No treatment with or without sulfanilamide produces beneficial changes in every case. Well over 90 per cent of cases can be assured of some improvement. Sulfanilamide therapy in combination with other drugs affords a method which may be used with reasonable activity without hospitalization and without the necessity of prolonged daily treatment and observation. One or more courses of sulfanilamide alone are apt to produce disappointing results. The specific remedy for trachoma is not yet found. The essential nature of the disease and its cause and its treatment remain a problem to be solved.

Surgical Management of Peptic Ulcer—Lahey and Marshall state that, of the 7,000 hospitalized patients with ulcer, 181 per cent were subjected to operation for gastric ulcer and 659 per cent for a duodenal ulcer. The mortality rate was 27 per cent for all gastric, duodenal and gastrojejunal ulcers, exclusive of the gastrojejunal fistula, it was 32 per cent for 251 subtotal resections of all types—gastric, duodenal, gastrojejunal and gastrojejunal fistula, it was 44 per cent in 46 consecutive subtotal gastric resections performed solely for a gastrojejunal ulcer. The authors discuss the surgical management of some of the more complicated peptic ulcers in the last 251 consecutive operative cases. The ulcer states which have been complicated and difficult to manage are the low duodenal ulcer involving the common bile duct in its indurated scar, the ulcer located at or below the entrance of the common duct in the duodenum, the gastrojejunal ulcer, the gastrojejunal fistula and the recurrent ulcer in the gastric stump after a high subtotal gastrectomy. All the deaths among the 251 patients subjected to total or subtotal gastrectomy for ulcer, with the exception of 1 patient who died of embolus, were of patients having ulcers of these complicated types. The authors stress that conservative operative methods are occasionally imperative to avoid high operative mortality in certain densely adherent duodenal ulcers or ulcers arising low in the duodenum and involving the common duct. Radical subtotal gastrectomy is necessary for relief of the surgical gastrojejunal ulcer. Temporizing operative procedures in view of the possibility of recurrent ulcer serve only to increase further the operative risk.

Sulfanilamides in Traumatic Peritonitis—Gilchrist and his associates produced peritonitis in dogs to ascertain the time necessary to establish adequate blood and intraperitoneal con-

centration of various sulfonamides after administration by mouth or vein, by implantation into the abdomen, and by intraperitoneal injection. They made 716 determinations of sulfonamide concentrations on the heart blood and peritoneal fluid in experiments on 75 dogs. The authors present observations on human material which correspond to the results in the animal experiments. Sulfanilamide given by mouth after injury to the peritoneum will not produce adequate early concentrations in blood and peritoneal exudate. A 10 per cent solution of sodium sulfathiazole may be injected intravenously without producing a phlebitis. Fifteen minutes after such an injection the effective sulfathiazole level in the peritoneum will approach that found in the blood. Therapeutic concentration in the peritoneal fluid will be maintained for four to six hours. If sodium sulfathiazole solution is injected into the abdominal cavity after the injury and before closure of the perforation, an immediate high concentration is obtained. When sodium sulfathiazole or sulfanilamide crystals are placed in the abdomen at operation there is a rapid high concentration of drug in the peritoneal exudate. The blood concentration rises to therapeutic levels rapidly and falls below such a level after six hours. When relatively insoluble sulfathiazole crystals are placed in the abdomen, effective concentrations are reached in the peritoneal exudate in twenty minutes and are maintained for many hours. The concentration in the blood rises slowly and usually remains below therapeutic levels. The following program for retarding the development of peritonitis after bowel perforation is suggested: 1. Five-tenths Gm of sodium sulfathiazole per 10 pounds of body weight should be injected intravenously (5 or 10 per cent solution) in from two to four minutes. Intravenous fluid, plasma, or blood should follow. As an alternate procedure a soluble drug or a suspension of sulfathiazole microcrystals may be injected directly through the abdominal wall or through the entry wound. Laparotomy should be performed as soon as possible. At that time a relatively insoluble sulfonamide, such as sulfathiazole, should be placed in the abdomen. When soluble sulfonamides are used in the abdomen, additional drugs must be administered after eight hours. When slowly soluble sulfathiazole is used in the abdomen, additional drugs need not be administered for twenty-four hours.

Roentgen Therapy in Gas Gangrene—McMillan collected from the literature 416 cases of gas gangrene in which roentgen therapy was used and reports 13 new cases in which this treatment was employed. Roentgenograms should be taken of the involved area every four to six hours in injuries where gas gangrene is liable to develop. This will lead to early diagnosis. The development of clinical signs and symptoms need not be awaited. Prophylactic treatment of wounds liable to develop gas gangrene should consist of immediate debridement, use of sulfanilamide in the wound and adequate doses of tetanus gas gangrene antitoxin. X-rays may also be useful as a prophylactic measure. Active treatment should consist of 100 roentgens over involved areas as soon as diagnosis is made or strongly suspected, repeated twice daily for three days or until the infection is brought under control, local debridement and therapeutic amounts of the antiserum if the infection is more than twelve hours old or if the patient does not respond clinically to the foregoing treatment. Amputation should not be resorted to for gas gangrene per se. Of the 416 patients given x-ray treatment 62 died, giving a mortality of 149 per cent. Millar's review of 607 cases before the era of roentgen treatment revealed a mortality of 497 per cent. Of the 13 new reported cases 3 had a fatal outcome.

Clostridium Welchii Infection Following Abortion—
At the Woman's hospital in Melbourne as many as twelve deaths in one year have resulted from fulminating infections due to *Clostridium welchii*. It is often present in the vagina, the uterine contents, the urine and even in the blood without causing symptoms of a severe infection. Thus mere isolation of *Cl welchii* from the tissues or body fluids is of little diagnostic significance. Butler showed that the strains of *Cl welchii* causing the severe infections differed from most of the strains obtained from patients who did not develop symptoms both in regard to growth characteristics and to the amount of capsular material produced in broth. The examination of smears from the cervical canal solved the problem of rapid bacteriologic diagnosis. In severe infection cervical smears showed heavily capsulated bacilli and considerable destruction of the leukocytes. This combination was not seen in the smears from patients who although infected with *Cl welchii*, did not show symptoms of a severe infection. This suggested that severe *Cl welchii* infections associated with abortion were caused by only certain variants of this organism. She studied more than 600 strains of *Cl welchii* isolated from abortifacient cases with regard to one or more of the following characteristics: capsulation in broth cultures, production of alpha toxin, phagocytosis by human leukocytes and pathogenicity of washed cultures for guinea pigs. Smears from the cervical canal were examined in 80 cases in which there was a proved *Cl welchii* infection. All the strains of *Cl welchii* causing the severe generalized infection possessed the properties of highly invasive variants and differed from both the strains causing localized infections and those cultivated from the blood of patients without symptoms of a severe *Cl welchii* infection. In the severe infections the patient's symptoms were correlated with the properties of the infecting strain. The comparative rarity of the severe infections was explained by the finding that the highly invasive

variants of *Cl welchii* formed only a small minority of the strains cultivated from the genital tract. All the strains causing the severe infections and also some of the control strains produced a fatal infection in guinea pigs when washed cultures from agar were injected intramuscularly. This property was sometimes lost comparatively rapidly under artificial cultivation. It is suggested that a somewhat similar correlation to that observed in abortifacient cases may exist between severity of infection and the characteristics of the infecting strain in gas gangrene following wounding.

Iron Media for Cultivation of Anaerobic Bacteria in Air—Hayward and Miles found that strips of sheet iron (which is a heat resistant, moderately pliable type of rolled mild steel) have a remarkably stimulating effect on the growth promoting properties of simple solutions of peptone for anaerobic bacteria. The mode of action of the iron is probably complex. The maintenance of a stock of dry strips of sheet iron is a simple matter, and broths or peptone waters from which air has been expelled by heating are converted by the strips into excellent "aerobic" media for biochemical tests or anaerobic bacilli, both sporing and nonsporing, and of anaerobic streptococci.

- *Bacillary Dysentery Caused by Bacterium Dysenteriae P274 L E Rothstadt, F Fenner and B A Baker —p 341
*Bacillary Dysentery Some Results and Conclusions from Series of Patients Treated with Sulfaguanidine R F West —p 344

Bacillary Dysentery Caused by Bacterium Dysenteriae P274—Rothstadt and his collaborators provide further evidence for the acceptance of P274 as a true dysentery organism. They review cases of dysentery treated at an Australian general hospital. Stools from 228 patients suspected of having bacillary dysentery were examined, and dysentery organisms were isolated from 85, as follows: *Bacterium dysenteriae* Flexner 39, *Bacterium dysenteriae* P274, 42, *Bacterium dysenteriae* Boyd I 1, *Bacterium dysenteriae* Sonne, 2, *Bacterium dysenteriae* Schmitz, 1. *Bacterium dysenteriae* P274 was not isolated from any patient not suffering from clinical dysentery and has not been reported to occur in normal stools in numerous examinations. The clinical picture of the disease caused by P274 is indistinguishable from that of acute bacillary dysentery due to *Bacterium dysenteriae* Flexner. The authors conclude that the organism P274 of previously unproved pathogenicity has satisfied the criteria necessary to secure its acceptance as a true dysentery bacillus. It is suggested that the organism should be named *Bacterium dysenteriae* Boyd IV.

Bacillary Dysentery Treated with Sulfaguanidine—West made a survey of 279 patients with diarrhea admitted to a hospital over a period of three months. Early diagnosis is important and in most cases it can be made from the history and from macroscopic examination of the stools. Laboratory methods are a help but are not necessary for diagnosis. Sigmoidoscopic examination is essential in all doubtful cases. Among the 279 cases there were 167 of acute bacillary dysentery, 12 of amebic dysentery and 100 of nonspecific enteritis. Limitation of bed space permitted complete treatment of only 97 of the patients with bacillary dysentery. Attempts at culture with 1 specimen of feces from each of the 97 patients yielded results in 46 (48 per cent). The types of organisms isolated were Flexner I, Flexner II, Shiga, Schmitz and Sonne. A control series of 23 patients were treated with sodium sulfate, the other 74 being treated with sulfaguanidine. Patients treated

with sulfaguanidine showed a pronounced improvement in their general condition after twenty-four hours, and on the third day their feeling of well-being was remarkable, this is in sharp contrast to those receiving saline therapy, who even at the end of seven days, and sometimes well into the second week, experienced abdominal discomfort, anorexia and malaise. The authors conclude that sulfaguanidine therapy should be used in all cases, mild or severe.

*Studies on Problem of Goiter Goitrogenic Substances in Plants and Sensitivity of Animals F Blum —p 1329
Treatment of Insomnia F Grote —p 1333

Goitrogenic Substances in Plants—Blum states that practically all members of the cabbage (Brassica) family except kale contain goitrogenic substances. Soy beans have a strumigenic effect as do also various beans which are members of the Phaseolus family, and peas and lentils, members of the Vicia family. There are indications that peanuts (Arachis) contain a strumigenic factor. He found that not only small animals like rats, guinea pigs and rabbits are likely to develop goiter in response to feeding with the aforementioned vegetables but also goats, sheep and hogs. Typical goitrous degeneration of the thyroid could be developed in dogs provided the feeding with cabbage was begun early enough and was sufficiently prolonged. Geese likewise developed characteristic thyroid changes.

Ergotamine Tartrate for Herpes Zoster—Fris-Møller found ergotamine tartrate highly effective in herpes zoster. Stokly administered 0.5 cc of ergotamine tartrate subcutaneously for six successive days in the treatment of 6 patients with herpes zoster. The results obtained corroborated those of the Danish author. With the exception of nausea and vomiting in 2 cases there were no untoward effects. Five of the 6 patients showed considerable improvement after the second injection. The peripheral circulation must be carefully controlled in the course of the treatment. Ergotamine tartrate is contraindicated in severe cardiac insufficiency and in Raynaud's disease. Stokly modified the dosage in 6 new cases by giving 0.5 cc on the first day and 1 cc daily after that until an effect could be noticed and then resumed the 0.5 cc dose. The total dose varied between 4.5 and 6 cc. The treatment was successful in all 12 cases.

- Bronchopulmonary Cancer Without Clinical Symptoms or X Ray Signs M R Castex and E S Mazzei —p 553
*Cervical Rib in Pulmonary Tuberculosis H Butori —p 558

Cervical Ribs and Pulmonary Tuberculosis—Butori observed 3 cases of cervical rib simulating pulmonary apical tuberculosis. He reviewed roentgenograms of 3,500 patients with pulmonary tuberculosis and found either a cervical rib or hypertrophy of the transverse process of the seventh cervical vertebra in the roentgenograms of 32 out of 1,100 women and of 12 out of 2,400 men, an incidence of 2.9 and 0.5 per cent for women and men respectively. The ribs were bilateral in 27 and unilateral in 12. The right bilateral rib was longer than the left in the majority of the cases. A right unilateral rib was more frequent than the left (7 to 5). The first rib

of either side showed abnormalities in 9 cases. These consisted of asymmetrical atrophy of the arch and of the presence of insertions of supernumerary muscles between the first rib and the cervical rib. Heredity and syphilis were not involved as causal factors. The Kahn serum test was negative in all but 2. There was no relationship between the type of pulmonary tuberculosis and the presence of a cervical rib. The existence of a cervical rib does not predispose to pulmonary tuberculosis. A cervical rib may simulate tuberculosis because of an area of dullness to percussion over the supraclavicular fossa, because of diminished respiratory excursions and because of certain subjective symptoms such as pain and nervous symptoms common to the two conditions.

Substances Inhibiting Carr-Price Reaction in Vitamin A Products—Catalan and Grande Covian state that cod liver oil and vitamin A preparations contain substances which inhibit the color reaction of the antimony trichloride color test of Carr-Price. They tried to obtain quantitative information regarding the inhibiting factors. They determined the inhibiting effect exerted by various quantities of chloroform dilutions of cod liver oil. The presence of substances inhibiting the Carr-Price reaction are of importance in the chemical evaluation of vitamin A, because of them the vitamin A content of some preparations may be underestimated and of others overestimated. If the vitamin A content of an oil is to be determined, it should be ascertained first whether it contains inhibiting factors detectable by saponification. A systematic study should be made of the distribution of inhibiting substances in various natural oils, which would establish the method to be employed in the evaluation of each particular oil. Commercial products of vitamin A often consist of vitamin A concentrates diluted in various types of oils. These oils may contain substances that inhibit the color reaction. Thus a change in the diluting oil may result in a noticeable change in Carr-Price color reaction although the vitamin A content is the same.

Vitamin E for Neuromuscular Syndromes—Puig Muset reviews observations reported by histopathologists on neuromuscular lesions resulting from diets deficient in vitamin E, as well as experimental investigations carried out by himself. He believes that vitamin E acts on the muscular system by fixing the phosphatides which form myelin. He deduces from this that, in order to be effective, vitamin E requires the presence of phosphatide reserves in the organism or the external administration of these substances. He regards lathyrism as a disease which exemplifies a deficiency in phospholipoids.

Meta-Amino-Parahydroxyphenylarsine Hydrochloride Hemialcoholate in Syphilis—Alcantara Madeira administered this substance to 150 adult patients with primary, secondary and tertiary syphilis. The drug was given intravenously in 0.04 Gm doses. The injections were given once a week for twelve injections. Two courses of injections were given one month apart. The treatment produced a rapid healing of primary, secondary and tertiary lesions and a rapid conversion of serologic tests. The drug was well tolerated.

Book Notices

New and Nonofficial Remedies 1943 Containing Descriptions of the Articles Which Stand Accepted by the Council on Pharmacy and Chemistry of the American Medical Association on January 1, 1943. Issued Under the Direction and Supervision of the Council on Pharmacy and Chemistry of the American Medical Association. Cloth Price \$1.00. Pp. 72. Chicago: American Medical Association, 1943.

New and Nonofficial Remedies for 1943 continues with minor improvements, the convenient and informative system of classification adopted for the 1942 volume. The terminology of the official drugs has been revised to conform to the U. S. P. XII and the N. F. VII. The valuable bibliographic index now appears on white instead of India tint paper, a wartime necessity. This index appears before the general index, which is now more properly placed at the end of the book. The new arrangement may appear at first somewhat awkward, but with a little use the wisdom and convenience of the changes become more and more apparent.

The chapter on digitalis and digitalis-like principles and preparations has been extensively and somewhat radically revised to keep pace with the changing attitude toward this drug. In this revision the Council had the aid of the foremost authorities on digitalis, including pharmacologists and clinicians. It is interesting to contrast the following sentence in the 1942 general article on Chaulmoogra Derivatives: 'The therapeutic properties of chaulmoogra oil appear to be due to these optically active unsaturated fatty acids of the chaulmoogric series, which in the 1943 edition reads: Any therapeutic properties chaulmoogra oil may possess would appear to be due to these optically active unsaturated fatty acids of the chaulmoogric series.'

Among the more noteworthy of the new editions are nikethamide, the central nervous system stimulant which was first introduced as coramine, diethylstilbestrol, the synthetic estrogen trichinella extract for the diagnosis of trichinosis and zephuran chloride, a mixture of alkyl dimethyl benzyl ammonium chlorides, an interesting new anti-infective agent.

The successive volumes of New and Nonofficial Remedies increase the profound respect everywhere tendered to the faithful and unselfish work of the Council on Pharmacy and Chemistry in the cause of rational therapeutics. Each volume represents a progressive milestone on the road of medical science.

Final Report, White House Conference on Children in a Democracy. Washington, D. C., January 18-20, 1940. United States Department of Labor, Children's Bureau Publication No. 272. Paper. Price 65 cents. Pp. 392. With Illustrations. Washington, D. C.: U. S. Government Printing Office, 1942.

This is the final report of the conference which met in Washington Jan. 18-20, 1940. Since its adjournment follow-up committees have been organized in twenty-six states and in Puerto Rico. The report outlines the point of view and perspectives of the conference and presents studies relating to child health and welfare in the American democracy. First there is a report on the numbers and distribution of children followed by a discussion of the American setting, rural and urban economic and cultural. The situation faced by children of minority groups is discussed with special reference to inequalities and discriminations. A chapter is devoted to the common needs of all children—parents, family life, dwelling, health, protection, education and training and preparation for later life. A chapter devoted to economic problems results in the interesting conclusion among others that 'one of the principal objectives of sound economic life in a democracy is that people shall be able to earn and administer their own incomes but over against this on the same page and part of the same set of conclusions, appears 'In pursuance of this function it would seem unavoidable for the government to assume a far larger and more responsible share in the direction of the national economy than has been the case in the past. The provision of services to the people so as to achieve a more equitable distribution of the wealth produced is only one way—although a very important one—of achieving that end. Education, leisure time activities and employment receive attention in lengthy chapters and so do social services for children.

The considerable space devoted to health will be of special interest to the doctor. The general tenor of the attitude of the conference seems fairly represented by the following:

It is coming to be recognized that a very large part of the population in addition to the indigent cannot from their own resources meet the expense of proper medical care and that in the long run it will pay the public to supply hospital accommodations, laboratory facilities and other diagnostic aids, use of therapeutic appliances, medical and nursing service and convalescent care for all the medically needy.

On this point the recommendations of this conference include the following specific statement:

The health and well being of children depend to a large extent upon the health of all the members of their families. Preventive and curative health service and medical care should be made available to the entire population, rural and urban in all parts of the country. A considerable portion of the population is able to obtain from its own resources all or part of the necessary medical service. Another large section of the population, however, consists of families whose incomes are below the level at which they can reasonably be expected to budget all the varying costs of illness without interfering with the provision of other items essential to the family's health and welfare; for these there should be available adequately supervised medical and dental care through a program financed by general tax funds, social insurance systems or such combination of methods as may be best suited to local conditions.

To achieve these ends will require expansion of full time local public health services organized on a city, county or district basis, construction and adequate support of health centers and hospitals, as needed especially in rural areas and more effective use of existing medical services and facilities, more effective coordination of community public health and medical services conducted by various agencies, public and private.

More money will have to be spent by government at all levels—local, state and federal. The responsibilities of each—administrative as well as financial—will have to be defined. The confusing array of agencies, public and voluntary, will have to be brought into a comprehensible system.

Nutrition. An Introductory Text. By Fern Silver, Supervisor of Home Economics, Lincoln High School, Albuquerque. Cloth. Price \$1.35. Pp. 168. With Illustrations. New York: D. Appleton Century Company, 1942.

This is a briefer outline of nutrition intended for home use. It has chapters on foods in relation to energy and growth—composition, fuel value, fuel requirements, protein and its uses, and digestion and absorption—minerals in relation to body nutrition, vitamins, planning an adequate diet, adequate diets for children and relation of adequate diet to health. There is a general knowledge test on nutrition, an appendix containing tables of food values, and an index. In general the material is useful and well selected. The section on vitamins could have been improved by reducing emphasis on the results of extreme vitamin deficiencies amounting to virtual absence. Xerophthalmia and beriberi are not seen often in this country, the speculation as to whether sciatic rheumatism may be due to vitamin B₁ deficiency is out of place in such a book. More emphasis on subclinical deficiencies and less on extreme deprivation would be more serviceable in a book intended for lay readers. The table of food values on pages 140-143 is exceptionally good, bringing together all the contributions of ordinary servings of common foodstuffs. The tables of food composition beginning on page 151 are less serviceable—calories per pound are seldom of interest, protein, carbohydrate and fat in percentages require too much mathematics for the average—or even the above average—home. The material in this book is excellent for nutritionists and advanced students, its presentation is not as practical as it could have been for the ordinary American home.

Synopsis of Pathology. By W. A. D. Anderson, M.A., M.D., Assistant Professor of Pathology, St. Louis University School of Medicine, St. Louis. Cloth. Price \$6. Pp. 661. With 311 Illustrations. St. Louis: C. V. Mosby Company, 1942.

From the author's preface: This volume is intended to fill a gap which has existed between the very elementary manuals of pathology and the abundant excellent larger textbooks and reference works. By the presentation of pathology in a compact and condensed form it is designed to be useful to the medical student to the dental student studying general pathology and to the clinicians who must maintain familiarity with the foundation sciences of medical practice. In the first edition of a textbook such as this one expects to find a certain number of errors and instances of disproportion. This book is singularly free from such defects. It is remarkably well balanced and admirably reflects the author's purpose. Approximately 23 per cent of the text is devoted to general pathology (of which 60 per cent deals with infectious disease), 5 per cent to oncology and 72 per cent to special pathology. Illustrations

are quite adequate and, for the most part, excellent. Seventeen tables are to be found throughout the text, e g on differential features of venereal lesions, vitamin deficiencies in man, inflammations and ulcerations of the intestinal tract and grading of carcinoma of the cervix, which present in schematic fashion and correlate various related pathologic entities. It is fortunate that, in spite of space limitations, the author has seen fit to include in the chapters devoted to special pathology a brief concise summary of pertinent anatomic and physiologic data and thus prepare for a more complete understanding of the abnormal. The selection of references which may be found at the end of each chapter is especially to be commended in that the majority of them date from 1940. In the opinion of the reviewer this textbook is excellent in all respects and accomplishes what the author intended.

Holt's Care and Feeding of Children Revised and Enlarged by L Emmett Holt II, M.D., Associate Professor of Pediatrics Johns Hopkins University Baltimore [Sixteenth edition] Cloth Price \$2 Pp 321 with 5 illustrations New York & London D Appleton Century Company, Inc 1943

This book has been standard ever since the first edition appeared half a century ago. Since that time many things have happened, and the Holts, father and son, and their manual have had a part in them. Infant lives have been saved, health and feeding problems have been conquered, until the problem is not so much keeping children alive as teaching them to live and learning to live with them. The latest edition of Holt's manual takes cognizance of behavior problems, and deals with them in the same simple practical way as with directions about how to wash diapers and how to feed the baby artificial formulas as ordered by the doctor. The manual is a question and answer book, and it covers literally everything that a young mother would want or need to know. This edition can be recommended as whole heartedly as previous ones have been.

Human Neuroanatomy By Oliver S Strong and Adolph Elwyn, Associate Professor of Neuroanatomy College of Physicians and Surgeons Columbia University New York Cloth Price \$6 Pp 417 with 320 illustrations Baltimore William Wood & Company 1943

This excellent book is a real contribution for the undergraduate as well as the graduate student. It is written on the premise that neurology is dependent on an accurate knowledge of anatomy as a basis for the intelligent diagnosis and localization of neural disturbances. With this premise the reviewer entirely agrees. There are twenty chapters. The first eight describe in detail the organization of the central nervous system with regard to embryology, histology, segmental distribution of the peripheral nerve elements and their significance. The next twelve chapters are devoted to the study of the architectonics of the central nervous system. Here one finds excellent gross and microscopic photographs of anatomic detail with a clearcut discussion of the relationship of the structures in the light of clinical experience. There are three hundred and twenty such photographs. There is a large bibliography. This is a good book and is highly recommended.

Vitamins and Hormones Advances in Research and Applications Edited by Robert S Harris Associate Professor of Nutritional Biochemistry Massachusetts Institute of Technology Cambridge Mass and Kenneth V Thimann Associate Professor of Plant Physiology, Harvard University, Cambridge Volume I With a foreword by E V McCollum Cloth Price, \$6.50 Pp 452 with illustrations New York Academic Press, Inc 1943

The contents of this book are not as general and all inclusive as the title may suggest, they are devoted to special considerations which give the volume added value. The chapter titles include choline—chemistry and significance as a dietary factor, the appraisal of nutritional states, physical methods for the identification and assay of vitamins and hormones, the chemical and physiologic relationship between vitamins and amino acids, the photoreceptor function of the carotenoids and vitamin A, the significance of the vitamin content of tissues, growth factors for protozoa, physiology of anti-pernicious anemia material, the intermediate metabolism of the sex hormones, the hormones of the adrenal cortex. All sections are prepared by investigators prominent in the respective fields. Some of the information is presented in unique fashion, some as a redigestion of previously known or suspected facts, all offers a worthwhile reference source for those interested in vitamins and hormones.

Sometimes a suspicion of the contributor's inclination in controversial subjects is apparent, but this does not detract from the usefulness of the book, for the critical reader it should do no more than stimulate further thought.

Doctors of the Mind The Story of Psychiatry By Marie Bevon Ray Cloth Price, \$3 Pp 335, with illustrations by Ruth Ray Boston Little Brown and Company, 1942

The book gives popular and vivid but withal reliable accounts of some phases of scientific and practical psychiatry in recent times. Certain noteworthy achievements in psychiatry are described, largely on the basis of personal observations and interviews with leaders in the field, coupled with results of research of past records of the literature. No effort is made to review systematically the basic history of psychiatry and neurology. That mental illnesses long regarded as incurable are now in some cases curable is emphasized hopefully and effectively.

Atlas of Obstetric Technic By Paul Titus M.D. Obstetrician and Gynecologist to the St Margaret Memorial Hospital Pittsburgh Cloth Price \$7 Pp 180, with 193 illustrations by E M Shackelford, Medical Illustrator, John C Oliver Memorial Research Foundation St Margaret Memorial Hospital St Louis C V Mosby Company, 1943

Titus presents the subject of obstetric technic in pictorial form. In addition there are sections on sterility and minor postpartum complications treated in the same manner. The illustrations were prepared from sketches made in the delivery and operating rooms, hence they are accurate. The author claims that the book has a function entirely its own, namely the teaching of both normal and operative obstetrics by visual means through the medium of carefully prepared illustrations. However, there are few illustrations which cannot be found in the standard textbooks on obstetrics. Nevertheless some of the intermediary steps shown in this book are not in the standard textbooks and they may prove helpful to many physicians and medical students. A few additional illustrations should have been included. These are illustrations showing the knee-chest and Trendelenburg positions for the immediate treatment of prolapse of the cord, local anesthesia for vaginal deliveries and cesarean section, and the use of a tracheal catheter or some other apparatus for the resuscitation of the newborn. The illustrations are magnificent and unsurpassable for purposes of instruction. Each step is clearly shown, and the person looking at them should have a perfect visual image of every operative obstetric procedure. Titus deserves great credit for preparing such a fine atlas because, when used in conjunction with one of the standard textbooks of obstetrics, it should prove to be most valuable.

Children Can Help Themselves The Normal Child's Health Behavior By Marlon Olive Lerrigo, Ph.D. Cloth Price, \$2.25 Pp 219 New York Macmillan Company 1943

This book was written for parents. In a narrative form the author introduces a sensible pair of young parents and shows by concrete examples how they reared their son. In respective chapters the reader sees David at 1, 4, 8, 12 and 18 months, then at 2, 3, 4, 5, 8 and 11 years. The customary health behavior of the child at these stages of development is portrayed in each chapter. In each are included the diet, sleep, training, exercise and mental development at these various stages. As David gets older his behavior is checked against that of his two favorite playmates. The aim of the book is to aid parents as they impart responsibility and self reliance to the offspring. The fascinating style of each chapter should hold the young parents' attention through the years.

Peresadka rogovitsy svezhim konservirovannykh i aksirovannykh materialom eksperimentalno i klinicheskoe nablyudeniya [By] O I Shershevskaya [Corneal Transplantation of Fresh Preserved and Fixed Tissues Experimental and Clinical Observations] Boards Pp 201 with 80 illustrations Novosibirsk 1940

The monograph by O T Shershevskaya, submitted for the degree of master of science, deals with the subject of transplantation of the sclera. The author has reviewed the literature on the subject very well. She reports her own experiments with transplantation of the sclera in rabbits, utilizing fresh and conserved as well as tissue fixed in solution or formaldehyde. Much credit is given to the pioneer work in this field by Filatov.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

SUDDEN DEATH AND ANESTHESIA—FUNDAMENTALS OF ANESTHESIA

To the Editor—A white woman aged 21, whose weight was 110 pounds (50 Kg) requested a tonsillectomy. Her past history was negative except that she had always been nervous. Preoperatively her heart lungs blood pressure and urinalysis were normal. The patient was given morphine sulfate $\frac{1}{4}$ grain (0.003 Gm) and atropine sulfate $\frac{1}{2}$ grain (0.0032 Gm) one-half hour before operation. Induction of anesthesia was begun with approximately 50 drops of chloroform and was continued with ether. No further chloroform was used. The operation was slightly prolonged. The anesthesia was rather light the pupils being moderately constricted and there being some motion of the eyeballs most of the time. In fact I found it difficult to maintain sufficient depth with ether vapor administered through an ether tube attached to a suction machine and had to supplement this because of movement of the patient's limbs, with drop ether on three different occasions. Ether was omitted entirely during the last fifteen minutes because of faulty respirations and pallor. The pupils did not dilate. During the last fifteen minutes of the operation the patient stopped breathing momentarily and respirations were easily started by the simple procedure of pressure on the sternum. Immediately on removal of the mouth gag and completion of the operation the respirations were Cheyne Stokes in type. They persisted thus until death by respiratory failure one and one-quarter hours after completion of the operation. The pupils were dilated between 2.5 and 3 mm. They dilated widely with the apneic phase and contracted with the hyperpneic phase. The heart action was good until the last. Nikethamide caffeine and epinephrine were given with temporary benefit but without interrupting the periodic character of the respirations. Is it likely that I am right in assuming that death was due to morphine idiosyncrasy? Could death under similar circumstances be caused by apnea resulting from partial and intermittent anesthesia and holding the breath during induction? Could the chloroform have influenced the result? In this case would atropine in the dose given decrease or augment the respiratory depression? Can any reliance be placed on pupil signs with the use of morphine and atropine or either drug alone? Should morphine be condemned as preoperative medication? I do not consider this an ether death because the respirations did not stop but became periodic the patient lived one and one-quarter hours after stappage of ether and the narcosis instead of becoming lighter with elimination of the ether became deeper and more profound. Does the literature record many deaths during ether induction from apnea? Can ether narcosis produce Cheyne-Stokes respirations? Have any similar accidents been recorded? Is it likely that the use of carbon dioxide-oxygen mixture (not available at the time) would have made any difference in the outcome? Is lobeline a more powerful respiratory stimulant than nikethamide? Sollmann states in his textbook of pharmacology that it is dangerous to give an anesthetic to a crying child because of the possibility of producing apnea. Has clinical experience borne this out? Is it advisable to give preoperative medication before tonsillectomy to infants and small children? Which is the safest sedative for preoperative use morphine or one of the barbiturates? Is carbon dioxide administration effective in overcoming apnea?

M.D. New York

ANSWER—Explanation of the sudden death of a healthy person is not always possible. The excitement attendant on such an occurrence often prevents accurate recording of events and their sequence. The fact that thorough postmortem examination has failed on many occasions to furnish proof of the cause of death is well recognized. Before attempting to answer the fourteen questions included in this communication it may be profitable to offer some general comment on anesthetic problems.

Incidental interference with the normal physiologic functions accompanying the state of anesthesia are the usual causes of morbidity and mortality rather than specific effects of particular drugs. In other words failure adequately to protect the functions of respiration and circulation during anesthetic depression is of vastly greater importance than is the choice of the drugs used or the doses administered. In this case no mention is made as to whether the anesthetist was able to maintain completely free and unobstructed breathing throughout the operation. Not infrequently respiratory obstruction is present during a tonsillectomy under general anesthesia unless an artificial airway is placed in the trachea. Even with minimal bleeding during such an operation, blood and mucus may pass through the trachea into the lungs and interfere seriously with the exchange of oxygen and carbon dioxide between alveoli and the blood. On the basis of the information given the most likely explanation of this accident would seem to be respiratory obstruction. In some patients the anatomic relation of the structures of the pharynx when the mouth is held wide open results in partial obstruction of the larynx. Inadequate depression of the reflexes in the throat may result in partial adduction of the vocal cords thus contributing a considerable degree of obstruction to breathing. Clotted blood or pharyngeal

secretion in the air passages in the lungs may prevent either partly or completely the exchange of atmosphere in a lobule, a lobe or even a whole lung beyond the obstruction. Any of these accidents may be superimposed on what would otherwise be an insignificant depression of respiratory exchange due to the central action of sedative drugs or of general anesthetic agents. Granted that such partial respiratory obstruction did persist during this operation, the cells of the centers governing respiration would suffer from lack of oxygen and from acidosis caused by accumulated carbon dioxide. The physiologic mechanism for the maintenance of normal breathing is dependent on these two factors, the tension of oxygen and of carbon dioxide. The possibility of such disturbances resulting in serious harm or even in death is appreciated by the experienced anesthetist.

In answering the specific questions as accurately as may be, page references are made to the book *Fundamentals of Anesthesia* published by the American Medical Association Press, 1942.

1 The effective dose of morphine varies with individuals. Rarely is an eighth of a grain found to cause alarming symptoms even in a 5 year old child (p 32 and following of *Fundamentals*).

2 Apnea or depletion of carbon dioxide can cause death only through the failure of breathing. Artificial respiration is the remedy. The opposite condition, sometimes called hypercapnia is much more likely during general anesthesia (p 21 and following).

3 Death during the administration of chloroform is possible but not under the circumstances described.

4 Atropine in usual doses is not a likely cause of respiratory depression. It increases the rate of breathing and decreases the depth. It tends slightly to decrease the respiratory depression from morphine for this reason (top p 37).

5 Whether morphine is used to advantage before inhalation anesthesia depends on the time interval, on the dosage and on recognition by the anesthetist of its pharmacologic effects (p 32). It may accomplish tranquility and allay fear. It carries the patient toward anesthesia, and the quantity of other drugs needed (ether for example) is reduced. The time of its maximum depressant effect on respiration is roughly ninety minutes after hypodermic administration. Hence it is rarely given within one hour of induction of inhalation anesthesia, so that depression of ether may not be superimposed on an unexpected depression from the opiate. However respiratory depression from the morphine may decrease respiratory exchange sufficiently to make saturation of the patient with ether difficult (pp 133, 134 and 135 of *Fundamentals*).

6 Death from apnea is likely only if respiration ceases in the presence of hypoxia and artificial respiration is not instituted.

7 Cheyne-Stokes respiration during ether anesthesia is usually due to hypoxia following respiratory depression or obstruction, usually the latter (p 19).

8 Similar accidents have been observed and recorded. They have often been considered the result of long continued obstruction to respiration and an inadequate supply of oxygen. The sudden relief of obstruction without adequate excess oxygen in the atmosphere and in the presence of drug depression of the respiratory centers results in a complicated physiologic condition which may be fatal.

9 The use of an atmosphere rich in oxygen might have been very useful in this case. It seems justifiable to believe that the use of oxygen or artificial respiration during the apneic periods and the establishment of free exchange by means of an artificial airway might have changed the outcome. Whether carbon dioxide would be of added value is a debatable point.

10 It is probable that neither lobeline, nikethamide nor any other stimulant would have had a beneficial result. Many anesthetists prefer artificial respiration to stimulating drugs because it is efficient and instantly available (chapter VIII, p 151).

11 During crying deep breaths alternate with breath holding. Irregularity of dosage results. Anesthetic drugs are administered to crying children without accidents. It is perhaps cruel but not 'dangerous' if proper safeguards are taken. To avoid the necessity of doing so many anesthetists administer to children sedative drugs preoperatively in rather large doses.

12 Some anesthetists consider it advisable to administer non-volatile drugs to children before tonsillectomy. Others do not. Factors other than age and weight must influence the dosage of depressant drugs administered to children (pp 51 and 52).

13 It cannot be said that morphine is 'safer' than one of the derivatives or barbituric acid. One ought to be familiar with the pharmacologic effects of the drugs which one uses and choose drugs and doses which will produce effects desirable to the patient to whom they are administered (pp 32 and 33).

14 Since acapnia results from excessive elimination of carbon dioxide (hyperpnea), administration of this gas should overcome the acapnia. However, rarely during inhalation anesthesia does excessive elimination of carbon dioxide occur. On the other hand, an accumulation of carbon dioxide in the blood and body tissues during anesthesia is almost impossible to prevent because depression and obstruction of respiration are so frequently present (p 23)

PROGNOSIS AFTER CORONARY OCCLUSION AND DEVITALIZED TEETH

To the Editor—A man aged 40 had a nearly fatal anterior coronary occlusion in December. Since that time he has been making as much recovery as we think could be expected and with the exception of occasional pain and some limitation is going about his business. Some years ago three Caldwell-Luc operations were performed on his right antrum. Since that time he has had a sensory disturbance of his right upper lip and the right lower part of his nose. The internist who took care of the patient during his cardiac difficulty advised that all foci be checked and removed. Two upper teeth on the right side of his head, bicuspid and first molar, have never given any known trouble and are perfectly sound to inspection and to x ray examination but will not give any response to vitality tests. The question which the dentist, internist and I do not feel competent to answer is: Should these two teeth be extracted or should they be left in? The patient, while perfectly willing to cooperate, is not anxious to have the teeth extracted unless there is very good reason for it, since their loss would require replacement by dentures in order to leave enough teeth for chewing. How good would you judge this patient's prognosis for life? The electrocardiogram following the attack showed definite changes in the chest leads. The limb leads showed no changes for several weeks and then showed a decreased amplitude of the R wave in the first lead and coving and inversion of the T waves in all leads. Since that time the limb leads have appeared normal except for some decreased amplitude. There never was any appreciable disturbance in the take-off of the ST segment in the limb leads. There was considerable such disturbance in the chest leads.

M D, Kansas

ANSWER—Despite the fact that some residual angina pectoris is suggested by the statement in the second sentence of the query and the necessarily guarded prognosis in any case of coronary heart disease, it is possible that this man may feel perfectly well after a few more months and live for a good many years if his heart is not appreciably enlarged and if he has the usual luck and takes reasonable care of himself. His age is in his favor. The electrocardiogram, although of some importance, should not be the preponderant factor in prognosis. It is not apparent that there exists the necessity to have the teeth removed for the sake either of his heart or of his face, simply because they are devitalized, though the heart would probably stand the operative procedure.

FAMILIAL ONYCHOLYSIS

To the Editor—A 6 months old child had two toenails on each foot grow away from the nail floor instead of adhering to it. The mother has had a similar condition all her life and it has proved a nuisance. Is there any way of so directing the growth of the nail by strapping or any other method that will eventually make it grow normally?

E T Wilkes, M D, Sunnyside, L I, N Y

ANSWER—Onycholysis, separation of the nail plate from its bed for a part of its extent, is one of the commoner diseases of the nails. It is most often secondary to skin disease, such as psoriasis, eczema, syphilis or verruca, involving the nail folds or nail bed, or to trauma and maceration as in the series of occupational cases reported by Templeton (H J Onycholysis, an Industrial Dermatitis, THE JOURNAL, Dec 26, 1931, p 1950). There are reports, however, of onycholysis of familial origin. These cases are frequently ascribed to familial endocrine disturbance, for onycholysis has been seen in hyperthyroidism and hypothyroidism, hypogonadism and hypopituitarism. Thyroid disturbances seem to cause it much oftener than the other endocrine dysfunctions, and E C Fox has given an excellent report of a series of such cases (Diseases of the Nails. Report of Cases of Onycholysis, Arch Dermat & Syph 41 98 [Jan] 1940). Of his 30 cases, 28 occurred in women, most of them with low basal metabolism. Of these 3 were secondary to psoriasis or lichen planus, and 3 others could not be observed long enough to judge the effect of the treatment. Of those who were treated adequately with thyroid, 3 failed to improve, 21 showed definite improvement and several of these relapsed when the treatment was stopped. Definite signs of deficiency of the thyroid may be wanting, yet the patient improves when given thyroid therapy.

Concerning the possibility of mechanical aid to correct this condition, the only reference which has been found was the recommendation of J Heller (Onycholysis, Handb d Haut- u Geschlechtskr, Berlin, Julius Springer, 1927, p 113) to bind

the nails with strong preparations of tar, ichthammol or salicylic acid. No report of the success or failure of such measures has been discovered.

OIL SOLUBLE SUBSTANCES FOR INTRAMUSCULAR INJECTION

To the Editor—Will you please tell me what is known regarding the absorbability of medical agents dissolved in oil and injected hypodermically or intramuscularly? For instance, can any dependence be placed in the acutely stimulating effect of camphor dissolved in oil and injected? Mexican doctors in general use this agent by this method in cases in which an acute stimulant is required, and I contend that it is an erroneous procedure.

J A King, M D, Santiago Papasquiaro, Mexico

ANSWER—There are in general three classes of oil soluble substances which are used for intramuscular injection. The first is soluble in oil but is insoluble in water and in tissue fluids. The second is soluble in oil and in tissue fluids but is insoluble in water. The third class is oil soluble volatile substances.

In the first case the substance is precipitated in the tissues and absorption is poor. It generally causes a local fibrosis, and painful nodules may result.

In the second class, as illustrated by mercuric salicylate and bismuth subsalicylate, the substance is soluble in the tissue fluids. They are carried through the lymph spaces and reach the interstices in the muscles, where they form droplets and may become almost encysted. The oil is later digested and the substance is gradually absorbed over a period of weeks. This gives a reservoir of the drug for continued absorption. Such drugs are usually given once a week.

In the third class volatile substances such as camphor may be absorbed independent of the oil. However, ampules of camphor have recently been omitted from N N R (THE JOURNAL, Feb 6, 1943, p 431).

POSITIVE SEROLOGIC TEST FOR SYPHILIS WITHOUT PHYSICAL SIGNS

To the Editor—A man aged 30 on routine preemployment examination was found to have a 4 plus Kahn and Wassermann reaction at a reliable laboratory. Careful physical examination, including x ray of chest and careful questioning, reveal no evidence of syphilis. Repeated blood serologic tests after several days remain positive. Assuming that this could be a false positive reaction, what is the maximum length of time I am ethically justified in waiting to start active treatment? It has been my observation and the opinion of several of my colleagues that many if not the majority of physicians in this locality would start active treatment immediately. Would I be legally liable if this person should develop a tertiary lesion in the interval of waiting to see if this reaction becomes negative?

M D, Missouri

ANSWER—A suggested method of study of the problem of biologic false positive serologic tests is contained in an article by Joseph Earle Moore, Harry Eagle and Charles F Mohr (Biologic False Positive Serologic Tests for Syphilis. III A Suggested Method of Approach to Their Clinical Study, THE JOURNAL, Nov 9, 1940, p 1602).

Among the points suggested in that paper is the performance of serial quantitatively titrated blood serologic tests over a period of time in order to determine whether the reagin titer is falling, as would be expected in most biologic false positive tests, or alternatively remaining stationary or rising, as would be expected in syphilis. Assuming that this type of observation is carried out, together with the other points mentioned in the article referred to, it is justifiable to wait for six months to start active treatment.

So far as is known, the question of legal liability in the event of development of a syphilitic lesion during the interval of waiting has never been determined. No opinion could be expressed of the action of a hypothetical court if and when such a case ever came to trial.

OPTIC ATROPHY NOT DERIVED FROM ATABRINE

To the Editor—Have you any information on the possibility of atabrine causing progressive optic atrophy? We have at present a soldier with optic atrophy which we believe may be due to this drug which he was taking while on Guadalcanal. All other tests have been negative. I shall appreciate any information which you may be able to give me pertaining to this subject.

Captain, M C, A U S

ANSWER—There are no recorded instances of any individual developing progressive optic atrophy following the use of atabrine. Complete observations are available on large immediate dosages as well as prolonged administration of the drug. It is probable that such a condition develops independently and is not associated with the drug.

PENICILLIN IN THE TREATMENT OF INFECTIONS

A REPORT OF 500 CASES

STATEMENT BY THE COMMITTEE ON CHEMOTHERAPEUTIC
AND OTHER AGENTS, DIVISION OF MEDICAL SCIENCES,
NATIONAL RESEARCH COUNCIL

CHESTER S KEEFER, M.D., BOSTON, CHAIRMAN FRANCIS G
BLAKE, M.D., NEW HAVEN, CONN., E KENNERLY MAR-
SHALL JR, M.D., BALTIMORE, JOHN S LOCKWOOD M.D.,
PHILADELPHIA, AND W BARRY WOOD JR, M.D., ST LOUIS

Our purpose in this report is to acquaint the medical profession with the results that have been obtained in the treatment of 500 cases of various infections with penicillin. All these cases have been treated by twenty-two groups of investigators¹ accredited to the Committee on Chemotherapeutic and Other Agents of the National Research Council, and the results of the treatment have been collected and summarized by the chairman of the committee, who acted for it and for the Committee on Medical Research. All the penicillin used in this study was provided by Merck & Company, E R Squibb & Sons and the Charles F Pfizer Company. The costs of the penicillin were covered by a contract of the Office of Scientific Research and Development on the recommendation of the Committee on Medical Research. A recent statement of the progress of efforts with respect to penicillin has been published in THE JOURNAL by Dr A N Richards, chairman of the Committee on Medical Research of the Office of Scientific Research and Development.²

The discussion of these 500 cases will be concerned with the over-all results in various groups of cases. Separate and detailed reports of cases will be made by the individual groups of investigators in due course of time.

SELECTION OF CASES FOR STUDY

In order to conserve valuable material and to gather as much information as possible in the shortest period of time, the committee restricted the use of penicillin to the treatment of the infections listed. It was necessary to limit both the number of patients treated and

the types of infection to be studied, since only small amounts of penicillin were available for clinical investigation. It was the responsibility of the committee to direct the study toward those infections that are most likely to occur in our armed forces and to those that are resistant to the sulfonamides. The infections selected were:

- 1 Staphylococcus aureus bacteremia
- 2 Local Staph aureus infections failing to respond to the sulfonamides
- 3 Streptococcal infections failing to respond to the sulfonamides
- 4 Pneumococcal, streptococcal and staphylococcal meningitis or empyema
- 5 Pneumococcal pneumonia failing to respond to the sulfonamides
- 6 Sulfonamide resistant gonococcal infections
- 7 Subacute bacterial endocarditis

MODE OF ADMINISTRATION

In the present investigation solutions of penicillin were given intravenously, intramuscularly and topically, including local injection into the pleura, pericardium and joints and into the subarachnoid space. In giving penicillin intravenously, constant infusions were used in many cases, whereas repeated injections at two, three or four hour intervals were employed in others. When it became necessary to continue treatment over a period of several weeks, it was necessary in many cases to use various routes of administration, including constant intravenous infusion and repeated intravenous or intramuscular injections. Some patients tolerated intramuscular injections better than repeated intravenous injections, others did not.

In the treatment of meningitis, empyema and surface burns of limited extent, penicillin was used topically, that is, injected directly into the subarachnoid space or the pleural cavity or applied locally.

CONCENTRATION AND VOLUME OF PENICILLIN

For intravenous use, concentrations of 1,000 Oxford units per cubic centimeter or less were used at each injection. When a constant intravenous infusion was used the concentration was varied, depending on the total dosage during a twenty-four hour period. The rate of injection in some cases varied from 5,000 to 10,000 units an hour day and night, that is, 120,000 to 240,000 units every twenty-four hours. In others smaller amounts of solution were injected. This was regulated so that the rate of delivery was between 75 and 100 cc an hour. The penicillin was dissolved in saline solution or 5 per cent dextrose solution and allowed to run into the veins slowly or injected directly into the rubber tubing at periodic intervals.

With intramuscular injections it is important to keep the volume as low as possible in order to avoid local discomfort at the site of injection. The usual practice has been to employ a concentration of 5,000 units per cubic centimeter. In general there was no local reaction, but there may be some local soreness at the site of injection in some patients.

DOSAGE

The total amount of penicillin administered in Oxford units has varied tremendously from one case to another. There were also many variations in the total amount given with each injection, the interval of time between injections and the total duration of the treatment. These are natural variables in the investigation of any new drug, especially when information is being accumulated with only a limited supply of valuable material in several different infections. At the beginning of our studies it was common practice to give 5,000 units intravenously every four hours day and night, that is, 30,000 Oxford units every twenty-four hours. This amount was found to be adequate in some infections but was totally inadequate in others. Indeed, the dosage schedule varied from 1,000 to 25,000 units per hour, depending on the kind and severity of infection. In view of the variation in the dosage schedule it will be well to outline the practice at the present time. Before presenting the details it should be said that the question of adequate or optimum dosage has not been clearly defined. The objective in treatment should be the maintenance of a sufficient concentration of penicillin in the blood to inhibit completely the growth of the individual infecting organism.

Various methods have been used to titrate penicillin in the blood serum and body fluids and exudates (Fleming,³ Florey⁴ and Rammelkamp⁵). They all have as their objective the determination of the amount of penicillin that will inhibit the growth of a constant number of a standard strain of hemolytic streptococcus or *Staph. aureus* or of the patient's own strain of infecting organism. When facilities are available, such methods should be employed in the treatment of individual cases in order to determine whether sufficient amounts of penicillin are being administered.

Other methods of assessing adequate dosage are the signs of clinical response. These must be followed with great care and should include not only the response of the temperature and pulse rate but also the change in constitutional symptoms, the results of blood culture and the effect on the local infection.

ABSORPTION, EXCRETION AND DISTRIBUTION

The absorption, excretion and distribution of penicillin has been studied by Rammelkamp and Keefer,⁶ and the literature on the subject has also been reviewed by them. Blood concentrations of penicillin and urinary excretion of penicillin were determined after the administration of 5,000 to 40,000 Oxford units by various routes. Their summary was as follows:

Intravenous injection of penicillin resulted in high initial concentration in the blood plasma, which was followed by an

abrupt fall. Traces of penicillin were found in the blood for thirty to two hundred and ten minutes after the injection, the length of time depending on the amount administered. The sharp fall noted in the serum concentration immediately after the injection was associated with an increased excretion in the urine. The average excretion after intravenous injection was 58 per cent of the administered dose.

Penicillin was rapidly absorbed when given intramuscularly and slowly absorbed after subcutaneous injections. Excretion in the urine was rapid following intramuscular injections and delayed after subcutaneous injections.

Absorption from the body cavities was delayed, and this was reflected in the slow excretion of penicillin by the kidneys. The total amount found in the urine was somewhat lower than that obtained following intravenous injection. Fluid aspirated from the pleural and joint cavities twenty-two and thirteen hours after the injection showed appreciable amounts of penicillin remaining.

Administration of penicillin by enteral routes showed that absorption from the duodenum was rapid, whereas oral and rectal doses were poorly absorbed. These findings may be explained by the inactivating effect on penicillin of acid and *Escherichia coli*. After oral, intraduodenal and rectal administration, the average amount excreted in the urine was extremely small.

In the presence of renal failure penicillin was not excreted rapidly, and as a result high concentrations were maintained in the blood stream after intravenous injections.

Studies on the distribution of penicillin showed that the substance failed to penetrate the red cells in significant amounts. In general the average concentration found in erythrocytes was less than 10 per cent of the plasma concentration. No penicillin was found in the spinal fluid, saliva or tears in subjects receiving it intravenously.

Rammelkamp and Helm⁷ have shown that human saliva, bile and succus entericus do not inactivate penicillin, but gastric juice destroys it rapidly at body temperature. The destructive action appears to be due to hydrochloric acid and not to pepsin. In 2 patients with pernicious anemia and achylia gastrica the absorption of penicillin, when administered by mouth, was greater than that of normal subjects.

Aside from the excretion of penicillin in the urine, there is good evidence that it is excreted by the liver, since it can be found in the bile in higher concentration than in the blood stream. None has been demonstrated in the gastric juice.

INTRATHECAL INJECTION

With regard to the intrathecal injection of penicillin, in normal subjects the substance is slowly absorbed and slowly excreted in the urine following the injection of 5,000 or 10,000 Oxford units.⁸ It may be detected in the spinal fluid for at least 31.5 hours after the injection of 10,000 Oxford units. There is some evidence that penicillin is slightly irritating to the normal meninges, and the injection of 10,000 Oxford units into the subarachnoid space may be followed by headache, vomiting, increased intrathecal pressure and pleocytosis in the spinal fluid. Smaller amounts cause less intense symptoms.

In patients with meningitis, absorption of penicillin from the intrathecal space is more rapid than in normal subjects, and a greater amount of that injection is excreted in the urine. Penicillin can be detected in the spinal fluid twenty-four hours after its injection.

We have been unable to detect penicillin in the cerebrospinal fluid after intravenous or intramuscular injection, for this reason it is well for the time being at least to use penicillin both intravenously and intrathecally in the treatment of meningitis.

PENICILLIN RESISTANT STRAINS

It has been demonstrated by Rammelkamp and Maxon⁹ that various freshly isolated strains of *Staphylococcus aureus* vary only slightly in their susceptibility to the antibacterial action of penicillin. When however a given strain of *Staphylococcus aureus* was grown in increasing concentrations of penicillin over a long period of time it was possible to make the organism resistant. These investigators were also able to demonstrate that an increase in the resistance of *Staphylococcus aureus* may also occur during the course of penicillin therapy for localized infections in man. Similar observations have been made by Florey and his collaborators⁴ and by Blake¹⁰.

Others¹¹ have shown that strains of pneumococci, staphylococci and hemolytic streptococci may be made resistant to penicillin by exposing them to it continuously for a long period of time both in vitro and in vivo. It is of considerable interest that penicillin fast strains of pneumococci are susceptible to the sulfonamides and that sulfonamide resistant strains of pneumococci are susceptible to penicillin. Moreover McKee and Houck¹² have shown that an increase in the resistance of organisms to penicillin is associated with a proportional loss of virulence, an observation that is in striking contrast to the retention of virulence by sulfonamide resistant cultures.

Obviously more information is needed concerning penicillin resistant strains and their mode of production, since it may aid one in interpreting the clinical results or failure. It should be reemphasized that, once a strain increases in resistance, it loses its virulence and seems to be changed permanently as far as penicillin is concerned, but it remains susceptible to the sulfonamides. Also resistance is produced only after continuous exposure to the action of penicillin.

METHOD OF PREPARING PENICILLIN FOR TREATMENT

Penicillin is supplied in ampules of 5,000 units, 10,000 units, 25,000 units, 100,000 units and 1,000,000 units. As penicillin is extremely soluble, it may be dissolved in small amounts of sterile, distilled, pyrogen free water, in sterile isotonic solution of sodium chloride or in 5 per cent dextrose solution. When large unit sizes are being used in hospitals, the contents of the ampule should be dissolved in water or saline solution so that the final concentration is 5,000 units per cubic centimeter. This solution should be stored under aseptic precautions in an ice box and made up freshly every day. Solutions for local or parenteral use may be diluted further, depending on the concentration desired.

A For intravenous injection

1 The dry powder may be dissolved in sterile isotonic solution of sodium chloride in concentrations of 1,000 to 5,000 units per cubic centimeter for direct injection through a syringe.

2 The dry powder may be dissolved in sterile saline solution or 5 per cent dextrose solution in lower dilution (25 to 50 units per cubic centimeter) for constant intravenous therapy.

B For intramuscular injection

1 The total volume of injections should be small, that is 5,000 units per cubic centimeter of isotonic solution of sodium chloride.

C For topical application

1 The powdered form of the sodium salt is irritating to wound surfaces and should not be used.

2 Solutions in isotonic solution of sodium chloride with a concentration of 250 units per cubic centimeter are satisfactory. For resistant or more intense infections this concentration may be increased to 500 units.

RESULTS OF TREATMENT

Staphylococcus aureus Infections with Bacteremia—

There were 91 patients with *Staphylococcus aureus* bacteremia. Death occurred in 34 cases (37 per cent) and no demonstrable effect was reported in 3 (3 per cent). In the remaining 54 cases there was complete recovery or striking improvement. All treated cases were included regardless of the amount of penicillin administered or the duration of the treatment. By present standards of treatment we know that many of these patients were inadequately treated with respect both to the total amount of penicillin they received and to the total duration of the treatment. A number of the patients were treated early in the course of our studies when very small amounts of material were available and when less was known about the dosage. It is well, therefore, to discuss separately the patients who recovered or improved and those who died or failed to improve.

It is well known that *Staphylococcus aureus* infections with bacteremia are always serious and carry a high fatality rate. The outcome in any instance is influenced somewhat by the age of the patient, the site of the infection and its accessibility to surgical drainage, and the presence or absence of other debilitating diseases.

Patients with the most favorable outlook, then, are those under 40 years of age who have an infection localized in an area that can be drained surgically. Patients with the most unfavorable outlook are those over 40 years of age or with an infection that fails to localize or cannot be drained surgically, and those with other associated diseases. Another important point in prognosis is the duration of the illness. It is well established that in most cases of fatal staphylococcal infection death occurs within ten to fourteen days after the onset of the bacteremia.

With this information as a background, it might be expected that the patients who will receive the greatest benefit from penicillin are those under 40 years of age without complicating diseases who are treated intensively early in the course of their infection.

Cases with Recovery or Improvement—Fifty-four (60 per cent) of the 91 patients in this group recovered or improved in a striking manner during treatment, so that recovery followed later. Thirty-six of these patients were under 40 years of age and 42 were under 50 years of age. The fatality rate in patients under

40 was 34 per cent, whereas in those over 40 it was 50 per cent. Forty-seven patients received penicillin for seven to twenty-one days, the average amount given being in the neighborhood of 500,000 Oxford units and the extreme ranges being 100,000 units in several infants and 3,465,000 units in some adults. As shown in table 2, there was recovery or improvement in 18 of 22 patients with acute osteomyelitis, in 9 of 10 patients with bacteremia without obvious port of entry, and in all 10 patients with infections of the skin and subcutaneous tissues. There were a number of other serious staphylococcic infections with bacteremia in which recovery or improvement took place (pneumonia, epidural abscess, burns, cavernous sinus thrombosis and meningitis).

Fatal Cases—There were 34 fatal cases of *Staph aureus* bacteremia. Fifteen of these patients (44 per cent) were over 40 years of age. Nine patients had acute bacterial endocarditis established at the beginning of treatment. They were treated over varying periods of time from four to fifty-two days and received from 270,000 to 2,340,000 units of penicillin. In no case was there even temporary improvement. In no case of *Staph aureus* infection reported so far has endocarditis developed after treatment has been started.

Three of the patients who died had bilateral suppurative pyelonephritis. They were all elderly. One of them had diabetes and bilateral perinephric abscesses and was treated only two days before death. Another patient received only 35,000 units on the day of death.

Three patients had extensive burns—that is, more than 50 per cent of the body surface—with infection and bacteremia. There were a wide variety of disorders in which the staphylococcic infection was only contributory and was controlled by the penicillin but in which death resulted from the primary disorder (aplastic anemia, uremia from sulfadiazine administration, pulmonary embolism, cancer of rectum and so on).

These fatal cases emphasize once again the seriousness of *Staph aureus* bacteremia in patients over 40 years of age, those with bacterial endocarditis and those with debilitating diseases. They also serve to stress the fact that early and adequate treatment is necessary to control infection.

Conclusions—In brief, 60 per cent of 91 patients with *Staph aureus* bacteremia recovered or improved under treatment, so that recovery followed later. Death occurred in 37 per cent, and no effect was observed in 3 per cent. In a group of such infections in which the fatality rate is so high, these results are very impressive, since the over-all fatality rate in this group without penicillin or sulfonamides is usually about 85 per cent. The results of penicillin treatment become more impressive when one remembers that among the fatal cases there were 9 cases of endocarditis and that 15 of the patients received treatment for less than seven days. Many were treated late in the course of the disease or received an inadequate amount of penicillin according to present standards of dosage. The failures only serve to emphasize the great importance of early diagnosis and immediate and adequate treatment. Adequate treatment should consist in giving enough penicillin to sterilize the blood and localize the infection, and in continuing it until signs of active infection disappear. This frequently requires between 500,000 and 1,000,000 units given over a period of seven to fourteen days or longer.

STAPHYLOCOCCUS AUREUS INFECTIONS WITHOUT BACTEREMIA

There were 137 patients with local staphylococcic infections without bacteremia treated with penicillin. Of these, 109 (80 per cent) recovered or improved, 11 (8 per cent) died and 17 (12 per cent) showed no demonstrable effect.

The various groups represented herein will be discussed separately.

Osteomyelitis—Of the 55 patients with osteomyelitis, 48 recovered or improved and 7 showed no effect. By "recovered or improved" it is meant that the wounds and sinuses healed completely while under treatment or the exudate was sterilized of staphylococci and the lesion was healing. In some cases the lesions have remained healed, in others they have recurred. The precise details and the number of recurrences will have to await the full reports of investigators and the passage of time, since no one who has had any experience with the treatment of acute and chronic osteomyelitis would be rash enough to make any final statements concerning the ultimate outcome of these cases until several years have passed.

One is justified in making the following statements. Following penicillin treatment the exudate decreases greatly in amount within a few days and organisms are quickly reduced in number. In a few cases the exudate obtained from the wounds is sterile within a period of a few days to a week and healing progresses rapidly, so that sinuses that have been present for months or years heal completely in two to three weeks.

Various routes of administration have been used, including constant intravenous injections, repeated intravenous or intramuscular injections and local treatment.

Empyema—Seven of the 9 patients with staphylococcic empyema improved or recovered following penicillin treatment. One patient showed no effect and another patient died. The latter received only two injections into the pleural cavity, totaling only 28,000 units, and was only 3 weeks old.

In the patients who recovered or improved, it was possible to sterilize the pleural exudate over a period of several days by injecting between 40,000 and 50,000 Oxford units directly into the pleural cavity. It is important not to use penicillin as an irrigating solution, since it requires contact between the organism and the penicillin over a period of several hours for a maximum effect to take place. Even when the exudate is sterilized, it is often so thick that it is necessary to employ thoracotomy for adequate drainage. Once an empyema cavity is drained, it can be kept sterile by injecting penicillin into it daily. It has not been possible in the experience recorded to date to sterilize empyema cavities by the intramuscular or intravenous route.

As an aid in the treatment of staphylococcic empyema penicillin is one of the best remedies available.

Infections of the Skin and Subcutaneous Tissues—In the discussion of staphylococcic infections of the skin and subcutaneous tissues with bacteremia it was pointed out that all 10 of the patients recovered. In this group of 23 patients 19 were greatly improved or recovered completely.

Of the patients who failed to show improvement, 1 had an abscess of the thigh, treated locally, 1 had extensive psoriasis with local staphylococcic infection of the lesions, 1 had a chronic ulcer of the skin and 1 had a chronic sinus of the skin, treated locally.

Of the 19 patients who recovered or improved, 7 received only local treatment varying from three to six days, with solutions of penicillin in concentration of 200 to 250 units per cubic centimeter on moist dressings. The total amount of penicillin used was small and varied from 2,000 to 25,000 Oxford units. The others received intravenous or intramuscular treatment for three to twenty-one days, and since most of them were over 50 years of age, with carbuncles or other serious infections, the results were impressive.

Parenteral and local treatment may be combined in many of these local infections but parenteral injections for any but the most superficial lesions are to be preferred. Early and intensive treatment is also desirable.

Burns—In the treatment of 9 patients with burns penicillin was used intravenously and locally. Local applications were used in preparation for skin grafting in order to reduce the number of organisms or sterilize the surface. Parenteral treatment was employed to prevent invasive infections. In the 4 fatal cases the treatment was given for four to seven days for extensive burns of the body and extremities.

Fatal Cases—The 11 deaths in this group were from empyema with pyopneumothorax (1 case), brain abscess (2 cases), burns (4 cases), multiple lung abscesses (1 case), reticulum cell carcinoma (1 case) and meningitis (2 cases). All these patients were desperately ill when penicillin was started, and in some the prognosis was definitely poor when one excluded the staphylococcal infection, such as the cases of extensive burns, the patient with the reticulum cell sarcoma and the patient with pyopneumothorax following resection of the esophagus.

STREPTOCOCCIC INFECTIONS OTHER THAN BACTERIAL ENDOCARDITIS

Thirty-three cases of streptococcal infections that were resistant to sulfonamide therapy were treated with penicillin. There were 23 due to the hemolytic streptococcus infections, 6 due to anaerobic streptococcus infections and 4 due to nonhemolytic streptococcus infections.

Hemolytic Streptococcus Infections—In vitro studies show that hemolytic streptococci are more susceptible to the action of penicillin than is *Staph aureus*. Of the 23 patients treated, 13 recovered or were greatly improved under treatment, 7 died, and no effect was observed in 3.

Two patients died following infections of the throat, with thrombophlebitis of the deep cervical veins (post-anginal sepsis). Two patients had meningitis, 1 had cirrhosis of the liver and 1 had chronic nephritis. In the latter 2 cases the blood stream was sterilized but death followed from the primary disease. In the seventh case there was a large subphrenic abscess and a deep abscess of the muscles of the chest wall following a stab wound.

Of the 3 patients in whom no effect was observed, there were multiple ulcers of the skin associated with group C hemolytic streptococci in 1, another was a carrier, and a third had numerous ulcers of the skin due to the microaerophilic streptococcus.

Anaerobic Streptococcus Infections—Of the 6 patients in this group 5 had anaerobic streptococcus infections of the uterus, 3 of these recovered and 2 died, 1 of a pulmonary embolus and the other of multiple abscesses of the lungs. The sixth patient had a skull fracture with meningitis and recovered.

Nonhemolytic Streptococcus Infections—There were 3 deaths in this group and 1 patient showed no effect. Of the patients who died, 2 had a brain abscess, 1 of them with meningitis following a chronic empyema, and the third had multiple abscesses of the tissues. The patient who showed no improvement had pyelonephritis with endocarditis.

PNEUMOCOCCIC INFECTIONS

The pneumococcus is extremely sensitive to the action of penicillin. The results of treatment of 76 cases of pneumococcal infection are listed in table 2. Most of the cases of pneumonia were treated by Dr W. S. Tillett who will report his results in detail elsewhere. It is plain from the reported cases that penicillin is another potent weapon in the treatment of pneumococcal pneumonia and many patients have recovered on less than 100,000 units given over a period of two to three days. Others have required more penicillin.

The results in the treatment of pneumococcal endocarditis were, on the whole, disappointing, although 1 patient treated under our direction recovered. The evidence for a bacterial endocarditis in this case was good since an aortic insufficiency developed several days

TABLE 1—Summary of 100 Cases

Diagnosis	No. of Cases	Recovery or Improvement	Death	No Effect
Staphylococcus aureus infections	223			
With bacteremia	91	54	34	3
Without bacteremia	137	109	11	17
Streptococcal infections	33

Meningococcal infections	2	1	1	
Miscellaneous infections	12	4	3	4
Totals	500	263	94	40

after bacteremia was detected, and the bacteremia persisted for several days after treatment was begun.

The results in the treatment of pneumococcal meningitis showed only 7 recoveries among 23 patients (30 per cent). In 2 the meningitis was accompanied by endocarditis. In many of the 16 fatal cases (70 per cent) the treatment was carried out with small doses given over a short period of time, and not all of them received penicillin intrathecally or intracisternally. Since Rammelkamp and Keefer³ have reported that penicillin does not penetrate the subarachnoid space, and since the most striking results have been obtained in patients who received both intravenous and intrathecal treatment there are good reasons for believing that better results will be obtained in the future, when patients are treated earlier in the course of the disease and when large amounts of penicillin are exhibited intravenously and intrathecally.

In the treatment of pneumococcal empyema the best results are obtained by injecting penicillin directly into the pleural cavity. Here sterilization of the exudate may be obtained, although the exudate may be reabsorbed very slowly. In some cases the process of reabsorption may be accelerated by aspiration or drainage of the cavity.

GNOCOCCIC INFECTIONS

The results of penicillin treatment of gonococcal infections have been extraordinarily good. Most of the 129 cases were treated by Dr J. F. Mahoney and his asso-

ciates of the United States Public Health Service and are being reported by them. The results were satisfactory in 125 cases, that is to say, there was freedom from symptoms and they were bacteriologically negative within nine to forty-eight hours after treatment with between 100,000 and 160,000 units. The dosage varied from 10,000 units every three hours for sixteen doses to 20,000 units every three hours for five doses or 25,000 units every three hours for three doses. The precise details of treatment of these cases are being studied in order to define the minimum dosage and the

so striking that only a few patients have been treated with penicillin. Five patients have been treated, with one death (20 per cent). The patient who died received no penicillin intrathecally. One patient who recovered received only parenteral therapy. The number of cases of meningococcal infection treated so far is so small that no definite conclusion can be drawn concerning the effectiveness of penicillin. The results are suggestive, however, that intravenous or intramuscular treatment is followed in some cases by recovery. It is likely that better results may be obtained by both parenteral and

TABLE 2—Detailed Summary of 500 Cases

* Four of these cases showed only temporary improvement

minimum time required to achieve the best results. It should be stressed that all these cases that responded to penicillin were those of sulfonamide resistant gonorrhea. Here, then, is a most potent weapon in the treatment of sulfonamide resistant gonorrhea, and it is not too much to predict that penicillin will prove to be one of the most effective agents in the treatment of a disease that causes great ineffectiveness in the armed forces and in the civilian population.

Meningococcal Infections—The meningococcus, like the gonococcus, is extremely susceptible to the action of penicillin in vitro. The results of treatment of meningococcal meningitis with the sulfonamides have been

intrathecal treatment. Additional experience is needed before any statements concerning the usefulness of penicillin in the treatment of these infections can be drawn with assurance.

SUBACUTE BACTERIAL ENDOCARDITIS

At the beginning of this study our committee realized that the requests for penicillin for the treatment of subacute bacterial endocarditis would be numerous. We were anxious to give it a thorough trial in a limited number of cases in order to determine whether it was effective in controlling the infection. It was decided therefore that 10 cases would be thoroughly treated

a pilot experiment, and if the results were not promising the experiments would be discontinued until larger amounts of penicillin became available. This policy was adopted because it was the opinion of the committee that the penicillin that was available should be conserved for the clinical investigation of cases of infection most likely to occur in wounded soldiers and sailors and in those infections in which penicillin was most effective.

Up to the present time 17 patients with bacterial endocarditis have been treated. There were 4 deaths (23 per cent). No appreciable effect on the course of the disease was noted in 10 of them (59 per cent). Three patients improved temporarily while under treatment, although 2 of these soon relapsed after treatment was discontinued. The amounts of penicillin used varied from 240,000 to 1,760,000 units over a period of from nine to twenty-six days. There is good evidence that some strains of organisms are slightly more susceptible to penicillin than others and there is also evidence that the blood stream can be sterilized temporarily, at least in some cases. On the whole, however, the results in the few cases treated were disappointing. It is possible that some of these infections with susceptible strains of organisms may be influenced favorably if treatment is started early in the course of the disease and carried on in an intensive manner. This our committee hopes to be able to do when much larger amounts of penicillin become available for clinical investigation.

MISCELLANEOUS INFECTIONS

There were 12 cases of miscellaneous infections treated with penicillin. There was no effect in 1 case of atypical pneumonia, in 1 case of multiple subcutaneous abscesses due to *Escherichia coli* and non-hemolytic streptococci and in 1 case of moniliasis. Two patients with actinomycosis and 1 patient with a putrid abscess of the lung died. One patient with agranulocytosis and 1 with *Micrococcus tetragenus* sepsis recovered. One patient with ulcerative colitis was improved temporarily, and a patient with a mixed infection in a subscapular abscess improved following local use of penicillin.

GENERAL COMMENT

From the experience recorded so far, penicillin has been found to be extremely useful in the treatment of infections due to the staphylococcus, the hemolytic streptococcus, the pneumococcus and the gonococcus. It has been tested most extensively in the treatment of staphylococcal and gonococcal infections. The staphylococcal infections have included infections with and without bacteremia, acute and chronic osteomyelitis, cellulitis, carbuncles of the lip and face, suppurative arthritis, pneumonia, empyema, septic compound fractures, burns and epidural abscesses. It has been of great benefit in those cases of infection that are resistant to the sulfonamides. Experimentally it is a potent agent in gas bacillus infections, but up to the present time there are no studies on human cases. It has not been effective in the treatment of subacute bacterial endocarditis.

To obtain the best results it is necessary to inject penicillin continuously or at frequent intervals for at least seven to fourteen days or longer. This is necessary because penicillin is excreted rapidly in the urine and a large part of that injected is lost within a few hours. To keep organisms in infected areas exposed

to the action of penicillin, then it is essential that enough be given so that this objective is attained. Experience shows that the amount needed and the frequency of injection will vary from one patient to another and from one infection to another.

With respect to dosage the following schedule has been found useful in the various infections and for the present is the one that is being recommended by our committee. These suggestions are subject to change depending on individual circumstances and cases.

DOSAGE SCHEDULE IN VARIOUS INFECTIONS

A *In Serious Infections Due to the Hemolytic Streptococcus, Staphylococcus Aureus or Pneumococcus With or Without Bacteremia*—An initial dose of 15,000 to 20,000 Oxford units should be given, with continuing dosage as follows:

1 Five thousand units every hour injected into the tubing of an infusing intravenous set or

2 Constant intravenous injection of a solution at a rate designed to deliver 5,000 to 10,000 units per hour. In a few cases it may be necessary to use larger doses.

3 After the temperature has returned to normal, the total dose in a twenty-four hour period may be reduced by half, but it should be continued for at least seven days after the temperature is normal.

TABLE 3—Reactions

Type of Reaction	No. of Cases
1 Fever	5
2 Chills and fever	12
3 Thrombophlebitis at site of injection	19
4 Urticaria	14
5 Gluteal tenderness at site of injection	5
6 Headache flushing of face	10
7 Tingling in testes	2
8 Pains in muscles	2

B *In Chronically Infected Compound Injuries Such as Infected Compound Fractures or Septic Infections of the Soft Parts*—An initial dose of 10,000 Oxford units should be followed by 10,000 units every two hours or 15,000 units every three hours parenterally, with local treatment as indicated. This schedule may have to be increased or decreased, depending on the seriousness of the infection and the response to treatment.

C *Sulfonamide Resistant Gonorrhea*—The minimum dosage schedule has not been worked out completely, 10,000 Oxford units every three hours intramuscularly or intravenously for twelve doses has been used with success. It is not unlikely that the same effect may be obtained with 20,000 units every three hours for five doses. The results of treatment should be controlled by culture of the exudate.

D *Empyema—Streptococcal, Pneumococcal and Staphylococcal*—Penicillin in isotonic solution of sodium chloride should be injected directly into the empyema cavity after aspiration or pus or fluid. This should be done once or twice daily, using 30,000 or 40,000 units, depending on the size of the cavity, the type of infection and the number of organisms. Penicillin solutions should not be used for irrigation. It requires at least six to eight hours for a maximum effect of penicillin, so that continuous action is needed.

E *Meningitis—Staphylococcal, Pneumococcal and Streptococcal*—Penicillin does not penetrate the sub-arachnoid space in appreciable amounts so that it is

necessary to inject penicillin into the subarachnoid space or intracisternally in order to produce the desired effect. Ten thousand units diluted in isotonic solution of sodium chloride in a concentration of 1,000 units per cubic centimeter should be injected once or twice daily, depending on the clinical course and the presence of organisms. Intravenous or intramuscular injections should be carried on at the same time.

F Pneumonia—The dosage schedule for pneumococcal pneumonia has not been worked out satisfactorily, but for the present it is well to give between 60,000 and 90,000 units a day for three to seven days. Recovery has followed with smaller doses, but the foregoing schedule seems necessary, at least in some cases.

TOXICITY AND REACTIONS

One of the remarkable features of penicillin is its relatively low toxicity and the extremely low incidence of a systemic nature. This is all the more remarkable in view of the fact that the material that is available for clinical testing at present is perhaps not more than 10 to 15 per cent pure penicillin. The reactions observed in the 500 cases are listed in table 3.

Chills and Fever—These were recorded in 12 cases and fever in 5. In several it was difficult to attribute these reactions to the penicillin, since chills and irregular fever were present before treatment was started and they continued for a short period following treatment. In others, however, it was plain that these reactions were definitely related to the injection of penicillin. This statement is supported by the observation that the injection of 10,000 units of penicillin from some lots caused chills and fever, whereas the injection of 5,000 units from the same lot caused no reaction. These reactions were transitory, and aside from the temporary discomfort to the patient they caused no difficulty. In a few patients who were afebrile before treatment was begun low grade fever varying from 100 to 101 F would occasionally occur and last for several days. This was noticeable particularly in those patients who were receiving penicillin in large amounts continuously.

Urticaria—Urticarial eruptions were reported in 14 cases. Their cause remains obscure, since in some of the cases the urticaria did not appear for several days after penicillin was discontinued, in others it did not recur when penicillin was again injected, and in still others it developed during the exhibition of it. Whether these reactions are due to some impurity in the penicillin cannot be stated at present. In several cases in which penicillin has been given after an attack of urticaria there have been no signs of recurrence. The urticaria usually disappears temporarily following the injection of epinephrine.

Thrombophlebitis—This complication at the site of injection was recorded in 19 cases. It has been noted with certain lots of material and is likely to occur when injections are made repeatedly and when concentrated solutions are used. There is also some individual susceptibility to thrombophlebitis, since in several of the reported cases penicillin from the same lot injected into 1 patient would be followed by thrombophlebitis, whereas it would cause no reaction in a second patient. Pain along the course of the vein during the injection of material has been complained of by some patients.

Miscellaneous Complaints—Transitory attacks of throbbing pain in the head, flushing of the face, tingling

in the testes, pains in the muscles and constriction in the chest have been observed. All these complaints last only a few minutes and disappear spontaneously. It has been found that some impurity carried over from the extraction process used to remove pyrogens was responsible for these reactions. Passing the solutions through a Seitz filter removed the substances, and recent lots of penicillin have not caused these reactions.

Aside from the patients who developed urticaria, there have been none who have developed any signs of sensitivity to penicillin. A number of patients have received several prolonged courses of penicillin at varying intervals of time, and in none of them so far have any reactions been observed to a second or even a third course of treatment.

SUMMARY AND CONCLUSIONS

From the study of 500 cases of infection treated with penicillin the following conclusions are justified.

Penicillin is a remarkably potent antibacterial agent which can be given intravenously, intramuscularly or topically. It is ineffective when given by mouth.

Following intravenous or intramuscular injection it is excreted rapidly in the urine, so that in order to obtain an adequate amount of potent material in the circulating blood and tissues it is necessary to inject penicillin continuously or at frequent intervals, that is, every three to four hours.

Penicillin has been found to be most effective in the treatment of staphylococcal, gonococcal, pneumococcal and hemolytic streptococcus infections. It has been disappointing in the treatment of bacterial endocarditis. Its effect is particularly striking in sulfonamide resistant gonococcal infections.

While the dosage schedule requires additional investigation, it seems clear that the average patient requiring intravenous or intramuscular injections for serious staphylococcal infections requires a total of between 500,000 and 1,000,000 Oxford units, and the best results have been observed when treatment is continued for at least ten days to two weeks. At least 10,000 units should be given every two to three hours at the beginning of treatment, either by continuous intravenous injection or by interrupted intravenous or intramuscular injections.

Satisfactory results are obtained in sulfonamide resistant cases of gonorrhea following the injection of 100,000 to 160,000 units over a period of forty-eight hours.

Patients with pneumococcal pneumonia frequently recover following the use of 100,000 units given over a period of three days. This is especially important in sulfonamide resistant pneumococcal infections. It may be necessary to give between 60,000 and 90,000 Oxford units daily for four to seven days to get a maximum effect.

In the treatment of empyema or meningitis it is advisable to use penicillin topically by injecting it directly into the pleural cavity or the subarachnoid space.

Toxic effects are extremely rare. Occasional chills with fever, or headache and flushing of the face have been noted. Urticaria has been reported and thrombophlebitis at the site of injection has been described.

MODIFIED PROTAMINE ZINC INSULIN
AN IMPROVEMENT ON STANDARD
PROTAMINE ZINC INSULINCOMPARATIVE STUDIES ON SIXTY-TWO
DIABETIC PATIENTS

CYRIL M. MACBRYDE, M.D.

AND

HAROLD K. ROBERTS, M.D.

ST. LOUIS

The protamine zinc insulin now generally employed has proved valuable in the treatment of diabetes, but it has become increasingly evident that for many diabetic patients it is not ideal for maintenance therapy. This paper is the report of clinical investigations with a new form of modified protamine zinc insulin which has revealed distinct advantages in a series of 62 patients.

The use of the slow acting standard protamine zinc insulin has permitted a reduction in the number of injections necessary in the great majority of cases of diabetes. It has also diminished the wide fluctuations in the blood sugar occurring with several daily injections of regular insulin. It was hoped that good maintenance therapy in nearly all cases of diabetes could be established with a single daily injection of protamine zinc insulin. This hope has not been realized. In the six years since its introduction in February 1937 much has been learned about the degree of diabetic control possible with this form of modified insulin. When given once daily, protamine zinc insulin exerts a relatively constant effect on the blood sugar operating in practically uniform degree throughout the twenty-four hours, but it does not have sufficiently rapid activity after injection to control the rise in blood sugar occurring after intake of food.¹ The time of injection of the daily dose of protamine zinc insulin and the relationship of the time of injection to meals have relatively little to do with the shape of the twenty-four hour blood sugar curve. The highest blood sugar values occur during the day after the intake of food, while the lowest levels are found during the fasting period of the night or early morning. In patients with mild diabetes requiring 40 units of insulin or less per day the rise in the blood sugar after meals may not be sufficient to be important. In many such cases a single dose of protamine zinc insulin daily establishes good control. When the diabetes is more severe, however, it is usually not possible to give enough protamine zinc insulin to prevent hyperglycemia after meals without causing hypoglycemia during the fasting hours of the night or early morning. Since a single injection of protamine zinc insulin may exert some effect for forty-eight hours or longer, the total amount of insulin acting at any one time is the sum of that being absorbed from two or three depots in which the precipitated material has been subcutaneously injected. The constant absorption of the insulin proceeds at the same rate during the night as during the day. In patients with severe diabetes the rise in the blood sugar level after meals is great and rapid. In the majority of such cases if enough of the slowly absorbed protamine zinc insulin is given daily

hyperglycemia after food intake may be prevented, but the total insulin effect will be excessive with resultant hypoglycemia during the night. If the total daily carbohydrate allowance should be divided into six equal parts and the patient fed every four hours day and night, wide fluctuations in the blood sugar could be prevented. With this program, food absorption would be slower and more uniform to correspond with the slowly and uniformly absorbed insulin. Since such frequent feeding is not practical, an approach to it has been widely adopted, four meals a day being given instead of three, the last at 9 or 10 p. m. Small night meals, containing some protein and from 10 to 30 per cent of the day's carbohydrate have made it possible to control the majority of patients with relatively mild diabetes with a single daily injection of protamine zinc insulin.

COMBINED THERAPY A COMPROMISE

Diabetes that is moderate or severe, however, usually cannot be controlled with a single daily injection of protamine zinc insulin, even when a relatively large night feeding is employed. This problem has been met in a fairly satisfactory manner by ourselves and others² by giving a large dose of protamine zinc insulin and a smaller dose of regular or crystalline insulin in separate injections before breakfast daily. Thus the prolonged activity of protamine zinc insulin is utilized to prevent nocturnal hyperglycemia, while the regular insulin tends to control the rise in the blood sugar after meals. It is usually possible to adjust the dose of protamine zinc insulin so that it will not be large enough to cause insulin reactions at night or so small as to permit nocturnal hyperglycemia. Although this method of "combined therapy," using both a slow acting insulin and a rapid acting insulin, works well in the great majority of relatively severe cases, two very serious objections can be brought against it. 1 It is a compromise method, still requiring two injections a day, even though both can be given before breakfast. One of the chief advantages of protamine zinc insulin is thereby partly nullified. 2 Combined therapy requires the manipulation by the patient of two very different forms of insulin, thus increasing the possibilities of error. One of the insulins is precipitated and must be mixed and for large doses is usually used in 80 unit strength, the other is clear, is given in smaller doses and is usually employed in 40 unit concentration. Therefore two different syringes with dissimilar calibrations are often necessary.

We have analyzed the histories of all the patients we followed and regarded as satisfactorily regulated during the three year period from Jan. 1, 1940 to Jan. 1, 1943. Patients who could not be brought under good maintenance control were not included in this group. Of the 219 patients who could be satisfactorily regulated 131 (60 per cent) needed only a single daily injection of protamine zinc insulin, while 88 (40 per cent) required combined treatment with separate injections of protamine zinc and regular insulin before breakfast daily. The average dose needed in the 131 cases controlled with protamine zinc insulin alone was 24 units. The average total daily insulin requirement of the

1 Ricketts H. T. Constancy of Action of Protamine Zinc Insulin. Am. J. M. Sc. 201: 51-59 (Jan.) 1941.

88 cases needing combined treatment was 62 units. During the last half of the three year period we have become increasingly dissatisfied with the degree of control obtainable in severe diabetes with a single dose of protamine insulin daily. Of the last 154 cases (regulated in the past eighteen months) 81 (53 per cent) were maintained with protamine zinc insulin alone, while 73 (47 per cent) required combined therapy.

It is evident that treatment could be greatly simplified for a large proportion of diabetic patients if a form of insulin was devised which would as the result of a single injection, exert an influence on the blood sugar similar to that exerted by a larger dose of protamine zinc insulin and a separate smaller injection of regular or crystalline insulin. This highly desirable insulin should have activity prolonged enough to control nocturnal hyperglycemia plus sufficient rapid activity to prevent excessive increase in the blood sugar following food intake during the day.

INVESTIGATIONS OF "INTERMEDIATE" INSULINS

A number of forms of modified insulin have been studied with the hope that one of them would prove to have just the proper proportion of prolonged to rapid activity, so that a single injection might take the place of the two separate injections now required for the great majority of patients with severe diabetes. Some of these modified insulins have shown characteristics more or less intermediate between those of market protamine zinc insulin and regular insulin. Among these are histone zinc insulin, clear (soluble or acid) protamine zinc insulin and globin insulin. A review of the clinical studies with these and the other forms of modified insulin so far investigated³ reveals that, in general, market protamine zinc insulin gives better control throughout the twenty-four hours and is more predictable and reliable. We have recently completed a carefully controlled series of comparative studies,⁴ with these conclusions. When compared on 18 patients, histone zinc insulin gave poorer diabetic control than that obtainable with market protamine zinc insulin. The desirable more rapid action was insufficient and there was less prolonged effect. Comparative studies on 11 patients with clear (acid) protamine zinc insulin revealed less satisfactory diabetic control than was secured with market protamine zinc insulin.

Since these forms of modified insulin were proving so disappointing, and because of the interesting observations of Wauchope⁵ and of Ulrich,⁶ we returned to the study of the modified protamine zinc insulins which can be prepared by combining protamine zinc insulin and regular insulin. In common with these and other workers we previously had found that, when the two forms of insulin are mixed in the proportions usually employed in separate injections in the combined method of therapy, all or practically all of the insulin is precipitated by the excess of protamine present. As a rule the doses of protamine zinc insulin utilized clinically when both types of insulin are employed are several

times as large as the doses of regular insulin. Thus, when 45 units of protamine zinc insulin is mixed with 15 units of regular insulin the resultant insulin preparation actually contains 60 units of protamine zinc insulin. Ulrich, however, demonstrated that when regular or crystalline insulin is combined with equal or smaller amounts of protamine zinc insulin the resultant insulin preparations have unmistakably more rapid action than protamine zinc insulin. The results obtained by these workers and our own studies led us to conclude that, by combining various proportions of protamine zinc and regular insulin, modified insulins may be prepared with various degrees of intermediate activity. This concept was supported by assays performed in the laboratories of Eli Lilly & Co., since reported by Peck,⁷ which revealed that, the larger the proportion of regular to protamine insulin used in preparing the modified insulin, the more prompt and intense and the less prolonged are the effects.

These premises were then adopted. 1 Since a graded scale of intermediate types of insulin can be produced by adding regular or crystalline insulin to standard protamine zinc insulin, the most widely applicable of such preparations should be selected for careful study. 2 Such a preparation should be standard and should not be varied from patient to patient, to keep the therapy of diabetes as simple as possible. 3 The desirable proportion of slow (protamine zinc) insulin effect to rapid (regular) insulin effect could be ascertained by determining the proportions found necessary to establish good control in those patients requiring combined therapy.

THE DESIRABLE PROPORTIONAL EFFECT

Eighty-eight of the 219 well regulated patients required combined therapy. The average ratio between the separately injected two forms of insulin was protamine zinc insulin 3 to regular insulin 1. More than 80 per cent of the patients were best controlled with a proportion between 2:1 and 4:1, and more than 60 per cent with a proportion between 2.5:1 and 3.5:1. It is interesting and important to note that Joslin⁸ also found that a large proportion (more than 50 per cent of those on insulin therapy) of a recently analyzed series of diabetic patients required combined therapy and that the average doses needed were 39 units of protamine zinc insulin and 13 units of regular insulin. Here again the ratio required is 3:1. Our studies and those of other investigators indicated that an insulin having 3 parts slow action to 1 part rapid effect would be widely useful.

It was decided to prepare, if possible, an insulin having 75 per cent slow activity and 25 per cent rapid activity and to compare the control of diabetes obtainable with such a preparation with that secured with the forms of insulin therapy now generally employed.

PREPARATION AND CHARACTERISTICS OF THE SPECIALLY MODIFIED PROTAMINE ZINC INSULIN

It was found that several preparations with approximately the desired proportional effects could be made by mixing various amounts of protamine zinc insulin and regular insulin. The resultant proportions of soluble to precipitated insulin, and therefore the relative rapidity of action, depend on the excess of protamine present, the amounts of the two insulins used and the

p_H Standard protamine zinc insulin contains in excess of about 40 per cent protamine zinc. Mixture of equal parts of the two insulins should therefore insure the combination of all this excess, leaving 60 per cent of the regular insulin (or 30 per cent of the total units in the mixture of equal parts) in soluble form. Centrifugation of such a mixture, however, reveals that all of the insulin is precipitated since the p_H is close to 5 the isoelectric point of insulin, as the result of combining regular insulin (p_H 3) with protamine zinc insulin (p_H 7.2). Slight changes either to the acid or alkaline side of p_H 5 result in an unknown amount of the insulin returning to soluble form.

To avoid this uncertainty, and since an insulin with the p_H of body tissues seems desirable equal parts of protamine zinc insulin and regular insulin were mixed with the p_H adjusted to 7.2. It was then found that an amount of soluble insulin closely approximating 25 per cent of the total insulin was present in the supernatant fluid after centrifugation. Chart 1 shows the effect of injection of the supernatant fluid from such a preparation made from 30 units of protamine zinc insulin and 30 units of regular insulin. The activity was in all respects similar to that exhibited by 15 units of regular insulin given to the same patient. Fifteen units of the special insulin preparation (25 per cent of the total 60 units) was in soluble form, while 45 units (75 per cent) was in the precipitate. Modified protamine zinc insulin so prepared was selected because of these desirable characteristics for comparative studies on patients with diabetes. After storage for many months its activity was unchanged, so it appears to be stable.

METHOD OF INVESTIGATION

Patients—Diabetic patients were chosen for study who were not suffering from any complications which would disturb regulation of the blood sugar. Comparative observations with the various types of insulin therapy were made on 24 patients in the hospital, each patient remaining in the metabolism ward for several weeks. When it was found that good results were being obtained with the special modified protamine zinc insulin, investigation was started on office and clinic patients. Thirty-eight outpatients served as subjects for comparative observations. Patients with mild diabetes were included, but a special effort was made to include a large number of patients with the more severe grades of the disease, since the best test of the new insulin would be on these patients. A carefully weighed diet was given to the patients in the hospital, the diet for each patient being unchanged throughout the period of study. Likewise, no appreciable variation in the activity of each patient was permitted during the observations. The only factor altered from one period to another was the character of the insulin. Similar efforts were made to control the diet and activity of the outpatients. Regulation in the latter group is necessarily much less accurate than that obtained under the close supervision of the staff of the metabolism ward. However, the control secured in ambulatory outpatients engaged in their usual occupations will reflect more exactly the clinical usefulness of any form of insulin. The ages of the 62 patients ranged from 18 to 74 years averaging 46 years.

Diets—The diets used were those thought to be best for each patient, according to the individual age, size, nutritional status, activity and total caloric requirement. Protein allowances per day ranged from 56 to 110 Gm.

fat from 30 to 180 Gm and carbohydrate from 140 to 220 Gm. In nearly all cases a night feeding was given at 9:30 or 10 o'clock containing approximately 20 per cent of the carbohydrate, the remaining 80 per cent being divided equally among the three main meals. In certain cases in which a definite indication was present a somewhat larger proportion was given at lunch and supper. The average patient received 150 Gm of carbohydrate daily, distributed as 40 Gm each at breakfast, lunch and supper and 30 Gm in the night feeding.

Insulins—The special modified protamine zinc insulin was prepared for us in the laboratories of Eli Lilly & Co. It is made by admixture of equal parts of protamine zinc and regular insulin at p_H 7.2. The effect of the supernatant fluid (soluble insulin) by rabbit assay is approximately 10 units to each 30 units of precipitated insulin effect. For convenience and clarity in the remainder of this paper, this special modified protamine zinc insulin with 75 per cent slow effect and 25 per cent rapid effect will be referred to as 3:1 insulin. The Lilly Company has labeled this insulin for experimental purposes 'Special Protamine Zinc Insulin' 40 or 80 units per cubic centimeter.

Chart 1—Comparison on nondiabetic patients of effect of 15 units of regular insulin with that of the supernatant fluid from 60 units of the 3:1 modified protamine zinc insulin. The blood sugar curves are similar.

Comparative observations of the control of diabetes secured with 3:1 insulin with that obtainable with protamine zinc insulin alone or when supplemented with regular insulin, were made in each case.

METABOLISM WARD STUDIES

Each patient was as carefully regulated as possible with diet and insulin. If the diabetes could not be controlled with a single daily dose of protamine zinc insulin, separate daily injections of protamine zinc insulin and regular insulin before breakfast were employed. Frequent blood sugar determinations were obtained, and careful quantitative urine sugar measurements were made in four separate periods daily: 7 to 11 a.m., 11 a.m. to 4 p.m., 4 to 9 p.m., and 9 p.m. to 7 a.m. Meals were given at 8 a.m., 12 noon and 5 p.m. Glycosuria was eliminated as completely as possible and an effort was made to bring the blood sugar within normal limits. All conditions were then kept constant including diet, activity and insulin dosage. If any complication appeared such as fever, infection, change in activity, mistake in diet or unaccountable change in tolerance, the data were discarded. After at least four to seven days of relatively stable blood

sugar levels, twenty-four hour blood sugar curves were determined. Blood for sugar determinations was taken at 7 30 a m (fasting), 10 30 a m, 2 30 p m, 7 30 p m, 12 midnight and again at 7 30 a m (fasting). The blood sugar values at 10 30 a m, 2 30 p m, 7 30 p m and at midnight each represent the level present two and one-half hours after the preceding meal. The constancy of these intervals lends meaning

Chart 2—Composite blood sugar curves showing better control of diabetes obtainable with the modified protamine zinc insulin

and importance to the twenty-four hour curves constructed from such determinations. If the fasting blood sugar levels at the beginning and at the end of each curve were not within reasonable proximity, it was concluded that stabilization with that particular program was not satisfactory and such curves were not included.

When all criteria had been met, reasonable stability obtained and a twenty-four hour blood sugar curve secured which represented the control obtainable with protamine zinc insulin alone, or with combined therapy employing separate morning doses of protamine zinc and regular insulin, an equivalent dose of 3 1 insulin was begun, all other conditions being left constant. A similar period was allowed for stabilization with the 3 1 insulin, and when this had been accomplished a twenty-four hour curve was obtained reflecting the control obtained with the 3 1 modification.

RESULTS

1 *Standard Protamine Zinc Insulin Alone Compared with 3 1 Modified Protamine Zinc Insulin*—Comparison of 13 patients studied in the hospital revealed better control in 10 of the cases throughout the twenty-four hours with 3 1 insulin than with standard protamine zinc insulin. In 2 cases the control was equally good with the two insulins, while in 1 case the standard protamine zinc insulin gave a better twenty-four hour curve. Statistical analysis of the individual figures obtained with the two insulins at 10 30 a m and 2 30 p m, at which times the greatest differences occurred, show a probable significance favoring 3 1 insulin of 0.969⁹. At 10 30 a m the average of the blood sugar values obtained with 3 1 insulin was 23 mg per hundred cubic centimeters lower than the average after standard protamine zinc insulin, and at 2 30 p m the average was 22 mg lower. Blood sugar values were consistently lower with 3 1 insulin throughout the day and at midnight, but the level of the fasting blood sugars was slightly higher (table 1). The characteristics exhibited by the new insulin modification are

desirable. The soluble insulin content resulted in somewhat lower blood sugars during the day after the intake of food. The fasting blood sugars were the same or slightly higher, showing that the fasting period during the night is adequately controlled, while there is less tendency to produce hypoglycemia than occurs with standard protamine zinc insulin. The 3 1 insulin did not produce a single instance of nocturnal hypoglycemia. The equal doses of standard protamine zinc insulin and of 3 1 insulin which were compared were 35 units in 3 instances, 30 units in 3 cases, 25 units twice and 15 units 5 times. The average dose was 24.6 units. Not only was there less variation in the blood sugar levels throughout the day with 3 1 insulin but the total insulin effect was greater. It seemed to be more effective unit for unit than standard protamine zinc insulin. No doubt this resulted from the fact that there was less fluctuation of the blood sugar, and less of the insulin effect was spent in bringing back an abnormally high blood sugar value toward normal. Similarly, fewer units per day are needed with standard protamine zinc insulin than are necessary with multiple injections of regular insulin, because of the greater relative stability of the blood sugar. Composite comparative curves have been constructed from the mean values of the blood sugar determinations secured throughout the twenty-four hours with standard protamine zinc insulin and with 3 1 insulin (chart 2). In this group of cases the 3 1 insulin gave definitely superior regulation.

2 *Combined Therapy Compared with 3 1 Modified Protamine Zinc Insulin*—The control secured with separate injections of protamine zinc insulin and regular insulin should theoretically be identical with that obtainable with the 3 1 modified protamine zinc insulin if the proportions of the protamine zinc insulin and regular insulin are 3 to 1. Although the average doses used for the 11 patients in the hospital were 45 units of protamine zinc insulin and 13 units of regular insulin (ratio 2.9 1), the individual doses employed ranged from 60 and 10 (6 1) to 35 and 15 (2.3 1). Table 2 shows the blood sugar values obtained throughout the

Chart 3—Composite blood sugar curves showing better control of diabetes obtainable with the modified protamine zinc insulin than with "combined therapy"

twenty-four hours with separate doses of protamine zinc and regular insulin as compared with those obtained with 3 1 insulin, the doses of the latter being equal to the combined number of units used with the two separate injections. In 7 of the 11 cases the regulation was better with 3 1 insulin, in 3 instances the control was better with combined therapy and in 1 instance the effects were approximately equal. The composite curves (chart 3) show similar contours, illustrating that the

⁹ The statistical analyses were done according to Fisher's formula. A result of 0.95 or greater indicates significance in the statistical sense which could not be due to error in random sampling.

desired effect of securing from a single injection results like those following separate injections of the two different insulins has been obtained. The fact that 3 1 insulin gave even better control, with somewhat lower blood sugars and less glycosuria throughout the twenty-

of insulin, the diet and all other conditions being kept as constant as possible. After a week the urine tests were compared with those obtained on the previous program, and sugar determinations were done on the fasting blood and that obtained two and one-half hours after exactly the same breakfast.

four hours in the majority of cases, was somewhat unexpected. No doubt this can be explained by the greater uniformity of the insulin action and by the fact that the 3 1 proportion actually met the needs of the patients better than the various proportions individually employed in the combined therapy. Statistically the probable significance favoring the 3 1 insulin was 0.958.

OUTPATIENT STUDIES

The hospital studies, which were performed first, showed that it would be safe to change outpatients from the usual forms of regulation to 3 1 modified protamine zinc regulation if the fact was kept in mind that the 3 1 insulin is somewhat more effective unit for unit. It had also been learned that the 3 1 insulin could be used in relatively large doses, 85 units for example, being substituted for amounts as great as protamine zinc insulin 65 units and regular insulin 20 units (cases 1 and 5, table 2). It was evident that the most important test of the new insulin would occur when it was used instead of the usual forms of insulin treatment for patients requiring large doses and engaged in their normal occupations. Comparative studies were done on 38 outpatients who were housewives, business men, mechanics, laborers and students ranging in age from 18 to 62. Quantitative urine sugar determinations were not possible in the outpatient group. Patients were instructed to record fasting, late morning and before supper urine tests as negative or 1 to 4 plus qualitative Benedict's reactions. In each case the best possible regulation was first secured with standard protamine zinc insulin alone, or with protamine zinc and regular insulin in separate daily injections before breakfast. After at least one week of relatively stable conditions, as illustrated by the patient's urine test record, blood for sugar determination was taken fasting and again two and one-half hours after the patient's usual breakfast. Then 3 1 insulin was substituted for the previous form

RESULTS

1 *Standard Protamine Zinc Insulin Alone Compared with 3 1 Modified Protamine Zinc Insulin*—Comparison of these two forms of insulin in equal doses on 8 outpatients revealed better regulation with the new insulin modification in all cases, as shown by decreased glycosuria, less tendency to high blood sugar values after breakfast and less fluctuation in control. The fasting blood sugar levels were somewhat higher in 6 of the 8 cases, showing the less prolonged action of 3 1 insulin. The blood sugar values after breakfast were lower in every case when 3 1 insulin was used, illustrating the desirable more rapid effect. The average blood sugar rise after standard protamine zinc insulin when determined two and one-half hours after breakfast was 81 mg, while that after 3 1 insulin was only 16 mg per hundred cubic centimeters (table 3).

2 *Combined Therapy Compared with 3 1 Modified Protamine Zinc Insulin*—Thirty outpatients were studied in this group, and in 26 of the 30 cases control obtained with 3 1 insulin was as good as or better than that secured with separate injections of protamine zinc insulin and regular insulin. In 4 patients the control was somewhat better with standard protamine zinc insulin. Theoretically the control should be identical if the proportion used in the combined therapy was exactly 3 1 and if the same doses of 3 1 insulin were used as the total employed in each case in the combined therapy. The doses employed were not exactly the same. Somewhat smaller doses of 3 1 insulin were used in some cases because of its greater effectiveness per unit. In the cases requiring 80 or more units

total under the combined treatment, amounts from 5 to 15 units less were employed when the change was made to 3 1 insulin. There were 10 such cases among the 30, from 70 to 75 units of 3 1 insulin being substituted for from 80 to 95 units of total insulin in the combined treatment, according to individual indications. The 30 patients selected for this comparative

study had the most severe diabetes under good regulation we have observed. Their cooperation was secured largely through the hope that one injection of the new insulin might be substituted for the two morning injections which all of them had needed.

The average dose of protamine zinc insulin required in the 30 cases was 51.3 units (range 30 to 70), and the average regular insulin needed was 16.6 units (range 10 to 25). The average ratio in this group was 3.1:1, corresponding closely with the average ratios in all our other groups of patients requiring combined therapy. The range of the ratios between the two forms of insulin required was 4.5:1 to 2.8:1. The average total protamine zinc insulin plus regular insulin requirement was 67.9 units (ranging from 40 to 95 units), while the average dose of 3.1 insulin substituted for the combined therapy was 65.6 units (ranging from 40 to 95 units). In spite of the fact that somewhat smaller doses were used in one third of the cases, the 3.1 insulin control was better than that obtained with combined treatment in 13 of the 30 cases, just as good in another 13 cases and less effective in only 4 instances. With the com-

bined treatment the average blood sugar level two and one-half hours after breakfast was only 28 mg. per hundred cubic centimeters higher than the fasting level, indicating good control. With the 3.1 insulin, however, the rapid part of the insulin action was even more effective, since the average 10.30 a. m. blood sugar value was only 18 mg. per hundred cubic centimeters higher than the average fasting blood sugar level. The fasting blood sugar values were satisfactory with both types of insulin therapy, averaging almost exactly the same, 139 mg. The blood sugar values in individual instances were very close also at 10.30 a. m., averaging 9.5 mg. per hundred cubic centimeters lower with 3.1 insulin than with the combined treatment (table 4).

COMMENT

The better regulation secured with the special form of modified protamine zinc insulin having 75 per cent slow effect and 25 per cent rapid effect can be explained by the fact that the characteristics of this insulin are designed to meet the requirements of a large proportion of diabetic patients. It seemed likely that this insulin, prepared especially for patients with severe diabetes requiring separate daily doses of protamine zinc insulin and regular insulin, would produce effects similar to those produced by the combined therapy. As shown by these studies, the results were similar, a

single dose of the 3.1 insulin not only giving control as good as that obtained by combined therapy but giving better regulation in most cases.

Less expected were the better effects of 3.1 insulin when compared with protamine zinc insulin regulation alone in milder diabetes. Decreased glycosuria and more stable blood sugar resulted in most of these cases. In no case was hypoglycemia observed. Hypoglycemia might have occurred had the rapid effect of the 3.1 insulin been excessive and would probably have been evident as low 10.30 a. m. blood sugar values. No such tendency was detected. Even when patients had been relatively well controlled with small doses of protamine zinc insulin the use of 3.1 insulin usually improved the regulation. Thus of the 5 cases requiring 15 units each in table 1 (cases 1 through 5) 3 showed better control with 3.1 insulin, while in the other 2 the control was as good as that obtained with standard protamine zinc insulin. The rapid insulin effect of 3.1 insulin in the 15 unit dose is 25 per cent of 15, or 3.75 units. When the 3.1 insulin was substituted for larger doses of protamine zinc insulin, the rapid insulin effect increased proportionately. For example, patients requiring 40 units got approximately 30 units slow effect and 10 units rapid effect, which for most patients seemed to be a convenient proportion and improved the regulation.

Colwell, Izzo and Stryker³ have obtained encouraging results with an insulin modification made by mixing 2 parts of crystalline insulin with 1 part of protamine zinc insulin, without readjustment of the p_H . In such a preparation all of the insulin is precipitated, but the activity is more rapid than that of protamine zinc insulin. Changes in the p_H , however, result in considerable alteration in the amount of soluble insulin which may be released in such a mixture. If mixed at p_H 7.2, for example, 50 per cent of the total insulin present is released in the soluble, quickly absorbable form. Since the p_H of the body tissues is approximately 7.2, there would seem to be danger of sudden absorption of a large amount of rapid acting insulin, with resultant hypoglycemia. We have observed this in a few patients treated with such a preparation. It seems safer to use 3.1 insulin, with the known p_H of 7.2, which is unchanged after injection. With 3.1 insulin the proportion of the precipitated to the soluble insulin is the same in the insulin vial as the proportion of the physiologic activities of the precipitated and soluble fractions after injection.

CLINICAL REGULATION SIMPLIFIED

To be of value clinically, a new insulin modification should not complicate the regulation of diabetes and should if possible simplify it. Treatment was greatly simplified in 34 of the 41 cases on combined therapy, since in these cases previously requiring two injections daily it was possible to substitute one injection of the modified 3.1 protamine zinc insulin. Clinical regulation is carried out as with standard protamine zinc insulin. The presence or absence of glycosuria before breakfast and before lunch and supper gives the most information. When combined therapy is used the absence of early morning glycosuria usually means that enough or too much protamine zinc insulin is being given. Glycosuria before breakfast usually suggests the need for an increase in the protamine zinc insulin dose. Absence of glycosuria before lunch and supper usually means that enough or too much regular insulin is being used. Glycosuria during the day requires an increase

in the regular insulin dose. With the specially modified 3:1 protamine zinc insulin, however, the fasting and postprandial urine tests are apt to change together rather than separately. When the amount of 3:1 insulin given is sufficient to prevent glycosuria at night there is apt to be little or no glycosuria during the day because of the proportional rapid insulin effect. Whenever glycosuria occurs during one part of the day while there is no sugar in the urine during most of the day, a slight change in the distribution of the carbohydrate allowance will usually suffice to reduce or abolish the glycosuria.

The 3:1 modified protamine zinc insulin was substituted with advantage both in cases requiring relatively small doses of insulin (usually protamine zinc insulin alone) and in cases requiring large doses of insulin (usually separate injections of protamine zinc insulin and regular insulin). Among the total of 62 patients there were 20 requiring 40 units or less of insulin daily, 14 requiring from 40 to 60, 18 from 60 to 80 and 10 from 80 to 95 units. Better control was obtained in all these groups with 3:1 modified protamine zinc insulin than with the usual methods of insulin regulation.

SUMMARY

A study covering three years and including 219 well controlled cases showed that a single injection of protamine zinc insulin as a rule established good regulation only in mild diabetes. The successful regulation of moderate or severe diabetes usually required separate daily injections of protamine zinc insulin and regular insulin ("combined therapy"). The proportion most widely useful was 3 parts protamine zinc insulin to 1 part regular insulin. Therefore a modified protamine zinc insulin with 3 parts prolonged action to 1 part rapid action was prepared. It is made by admixture of equal parts of protamine zinc insulin and regular insulin at pH 7.2. Comparative studies of the new insulin were done on 62 patients. These showed that a single injection of this 3:1 insulin modification gave a good control or better control than that obtained with combined therapy in 34 of 41 cases. In 20 of 21 milder cases the new insulin modification gave results as good as or better than those secured with a daily injection of protamine zinc insulin.

CONCLUSIONS

1. A modified protamine zinc insulin having 75 per cent slow or precipitated insulin effect to 25 per cent rapid or soluble insulin effect can be substituted with advantage for the forms of insulin now employed in maintenance therapy of diabetes. Since the effects of this insulin are more closely adjusted to the requirements of most patients with diabetes, better control is possible with it than with standard protamine zinc insulin. A single injection daily should permit good regulation in the great majority of cases.

2. The use of multiple forms of insulin should be discouraged. Good therapy of diabetes requires simplicity. Two forms of insulin should be sufficient. (a) A modified protamine zinc insulin such as that used in these studies. Such a modified insulin might well be substituted for the standard protamine zinc insulin now used, because of the better results in controlling uncomplicated diabetes. (b) Regular (or crystalline) insulin for use in diabetic emergencies and whenever supplementary insulin is required.

PROTAMINE ZINC INSULIN MODIFIED FOR ACCELERATED ACTION

ARTHUR R. COLWELL, M.D.

AND

JOSEPH L. IZZO, M.D.

EVANSTON, ILL.

In the routine treatment of diabetes mellitus it is often necessary to use simultaneously two types of insulin with different timing and intensity qualities of action. Protamine zinc insulin with its desirable slow, weak and prolonged effects must often be supplemented by separate injection of soluble insulin with its equally desirable prompt, intense and brief effects.¹ The separate use of these two types is often necessary in severe diabetes because protamine zinc insulin in dosage low enough to avoid hypoglycemia between meals or at night usually permits glycosuria after meals. Supplementary injection of insulin in solution either "regular" (amorphous) insulin or solution of zinc insulin crystals, helps to control postprandial glycosuria and is less likely to cause insulin shock during sleep because of its brief action. In small amounts it cannot be mixed with protamine zinc insulin because it is precipitated with loss of prompt effectiveness.

The use of two insulins simultaneously is confusing and involves multiple subcutaneous injections. It is necessary because the prolonged timing and intensity characteristics of protamine zinc insulin were not analyzed carefully enough in the course of its commercial development. Modification of it into an ideal preparation for daily use is a simple matter. In such an improved form therapeutic results are far more satisfactory than with orthodox methods. The reasons for this point of view are the subject of the present report. In preface it may be profitable to review some of the important factors leading to the development of protamine zinc insulin in its present commercial form.

PROTAMINE ZINC INSULIN

Composition.—Hagedorn's² original selection of a protamine to precipitate insulin into a suspension suitable for depot injection was based on the presumption that the greater its insolubility the more useful it would be in treatment. Therefore he chose a protamine which, when precipitated by insulin, is least soluble at the hydrogen ion concentration of human serum of all the protamines studied.

Proportions of insulin and protamine were selected which would yield complete precipitation of insulin at the point of least solubility of the compound. In fact an excess of protamine was and is used to insure maximum insolubility. This excess may vary somewhat in the products of different manufacturers. American products contain about double the amount necessary for complete precipitation when buffered to a pH of 7.2 to 7.3 or from 0.75 to 1.25 mg. per hundred units of insulin.³ Thus a preparation of greatest possible insolubility is formed which releases insulin for one to three days from a single depot.

3. Protamine Zinc Insulin. U.S. Nat. and Nonofficial Remedies, 1941, p. 293.

The addition of zinc to protamine insulin, used primarily for the purpose of increasing its stability and preventing cohesion of the precipitate in heat, prolongs its action still further. As shown by Scott and Fisher and others,⁴ zinc and other heavy metals possess the property of prolonging the effect of any insulin mixture. Thus protamine insulin, originally designed for maximum insolubility, was made even more insoluble with zinc, its present marketed form containing about 0.2 mg of zinc per hundred units.⁵

Therapeutic Virtues and Faults—The practical application of such a suspension in diabetic therapy certainly involves many advantages. By its use multiple injections are reduced, glycosuria is better controlled on the average, violent insulin shock is less frequent, acidosis is less likely to occur, and general health and nutrition in severe diabetes are improved.⁶ Yet experience reveals certain well defined disadvantages inherent in a preparation of such insolubility, all due to slow or uncertain absorption.

Because of its slow, weak and prolonged effect extending over a period of several days, daily depots yield a continuous

Second, even though the dosage is constant, the action is often unpredictably variable. Probably because of variations in rates of absorption from different depots, unexpected waves of glycosuria or hypoglycemia tend to appear, causing an undulating type of control in spite of constant conditions of therapy.⁸ Because these irregularities are unpredictable, they are not manageable by supplementary injections of soluble insulin. Too often they magnify the characteristic action of protamine zinc insulin, i. e., nocturnal fasting hypoglycemia or postprandial glycosuria.

MODIFICATION OF PROTAMINE ZINC INSULIN

Both in Denmark and in this country early investigators had insight into these timing factors. Most of the preliminary studies by Hagedorn and his colleagues were made with preparations containing no added zinc but excesses of protamine. Even when injected twice a day in efforts to adjust to feeding and fasting, these slightly less insoluble preparations permitted greater reduction of sugar during the night and poorer control after meals.² Appreciating their probable disadvantages, Krarup⁹ reported a single experiment with insulin 341 "the effect of which is both quick and of long duration. It is prepared so as to contain in the same volume twice as many units of insulin as are ordinarily used." This was the first reported action of a protamine mixture with intermediate action comparable to that of similar modifications to be reported.

Root, White, Marble and Stotz¹⁰ also pointed out that "it would be advantageous to have an insulin preparation—perhaps a slightly less insoluble protamine insulinate than the one now used—the action of which combines the desirable effects of both the 'old' and the 'new' insulin. Dr. Hagedorn writes that active work along this line is being continued in his laboratory."

These early suggestions have been followed up by Ulrich using mixtures containing 3 parts of soluble insulin and 2 parts of protamine zinc insulin,¹¹ and by ourselves using greater excesses of soluble insulin.¹² It is possible to modify the action of commercial protamine zinc insulin by the addition to it of excesses of soluble insulin. Its action is thereby accelerated to the extent that daily morning injections yield more insulin when needed during the feeding period of the day and less at night during fasting. Because such modifications are more soluble than standard protamine zinc insulin they also are somewhat more uniform in the effect of repeated single injections, although not so much so as soluble insulin. Thereby unpredictable variations in consistency of control are reduced and clinical usefulness is improved. Composite blood sugar curves in stabilized diabetic patients illustrating the action of single doses of protamine zinc insulin, soluble insulin and two intermediate mixtures of the two containing excesses of the latter are shown in chart 1.

Comparison of Mixtures Made with Crystalline and Regular Insulin—Subsequent study of intermediate preparations confirms the essential timing and intensity properties previously reported for such modifications in many cases. Because of its eight to sixteen hour peak

Chart 1—Variable timing and intensity characteristics of soluble (regular) insulin, insoluble (protamine zinc) insulin, and modifications of protamine zinc insulin containing less protamine in proportion to the insulin. The lower series of curves are arbitrarily smoothed replicas of the actual curves shown above. The modification marked 2:1 is the one chosen for therapeutic trial in the group of 60 cases reported.

supply of insulin at undulating basic levels characteristic of the individual and dosage. Two difficulties arise from this source.

First, the continuous supply fails to allow for intermittent feeding and fasting habits, so that glycosuria tends to follow meals and hypoglycemia tends to appear during fasting, particularly at night or if the morning meal is delayed.⁶

Supplementary injection of soluble insulin partially corrects these faults, but multiple injections again are involved, the very thing that protamine zinc insulin was designed to avoid. Small supplementary doses of soluble insulin are ineffective if mixed with larger amounts of protamine zinc insulin because the excess of protamine in the latter immediately precipitates insulin added to it, thus increasing the dose of protamine zinc insulin by the amount of insulin added.⁷

action and satisfactory twenty-four hour intensity, the modification made by mixing 2 parts of soluble and 1 part of protamine zinc insulin (2 to 1 mixture) was selected for detailed study and therapeutic trial.

The curves shown in chart 2 illustrate the response of the blood sugar concentration to single doses of two variations of this modification. Three patients with mild diabetes were fed every four hours night and day. Meals of approximately equal value eventually led to relatively constant high preabsorptive blood sugar levels. When such constancy was established, single injections of the insulin to be tested were given and the blood sugar was determined every four hours until the effects waned.

Twelve observations were made with mixtures containing 2 parts of regular insulin and 1 part of protamine zinc insulin. These responses were compared with sixteen other observations of mixtures containing 2 parts of solution of zinc insulin crystals and 1 part of protamine zinc insulin. Both preparations were used in the U-80 strength only, and all ingredients were products of the same manufacturer.¹³ Previous study has demonstrated the stability of such modifications when mixed in the ampule prior to injection¹² so all mixtures were prepared in that manner. The first three sets of curves represent averages for two to six responses to identical doses of the same preparation in the same patient.

Because of slight variations in control levels, all values were calculated in percentage of control levels for each modification and are averaged as shown in the lowest curve.

The results show a slight but measurable difference in the intensity of the two preparations containing the same proportions of soluble and protamine zinc insulin. Those made with regular insulin were slightly more prompt and 10 to 20 per cent more intense eight to sixteen hours after injection than those made with crystalline insulin. A measurable difference does not appear at twenty-four hours or thereafter. Judging from other unreported studies, the preparation made with 2 parts of regular insulin appears to resemble one containing about $2\frac{1}{2}$ parts of crystalline insulin and 1 part of protamine zinc insulin.

This slightly more intense peak action of mixtures made from regular insulin can be explained on the basis of its content of inert protein, as suggested by Peck.¹⁴ "Regular" or amorphous insulin yields only about 22 units per milligram on assay compared with 26 units per milligram from purified crystalline products. This is because amorphous insulin contains 10 to 20 per cent inert protein not contained in crystalline insulin. Protamine is a general protein precipitant. Therefore part of the excess protamine entering amorphous insulin mixtures precipitates the small fraction of inert protein, thus reducing the amount of protamine available for insulin precipitation. The net result is more soluble insulin and more intense action than in mixtures made with recrystallized insulin, in which all available excess protamine precipitates insulin, slowing and weakening the action of the mixture.

This difference is probably not of much practical importance. We have used both modifications in clinical therapy, frequently comparing their effects by transfer from one to the other in the same patient. With the regular 2 to 1 preparation there is a slightly greater

tendency to afternoon hypoglycemia than with the crystalline 2 to 1 mixture and in some patients better control of postprandial glycosuria. But these differences are negligible compared with the smoothness and consistency of control obtained with either of them contrasted with protamine zinc insulin or any combination of it with soluble insulin by separate injection.

THERAPEUTIC APPLICATION OF IMPROVED PROTAMINE ZINC INSULIN

These two insulins containing 2 parts of soluble (regular or crystalline) insulin and 1 part of protamine zinc insulin, varying only slightly in their accelerated action, were used for routine treatment of a group of 60 patients with severe diabetes mellitus for variable periods up to more than a year. The results appear to justify the use of such a modification in severe diabetes, in which the faults of ordinary protamine zinc insulin are most apparent. The advantages are equally applicable, although less essential, in the more easily controlled, milder forms of the disease.

METHOD OF TREATMENT

Patients.—Sixty diabetic patients were selected for therapeutic tests with the modified insulin. Almost all had established diabetes of greater than average severity. Two thirds were less than 40 years of age, about one fourth less than 20, the youngest was 2 years of age and the oldest 73. The average duration of diabetes for the group was 9.1 years.

Previous Adjustment.—More than 40 of the 60 patients previously had used more than 40 units of insulin daily. The average daily dosage for the entire group was 53 units. Fifty-two of the 60 had used protamine zinc insulin in a single morning dose. Thirty-eight of these had used small supplementary doses of soluble insulin in addition, usually in a single morning injection, rarely twice daily.

Their diets provided maintenance calories and protein and intermediate carbohydrate to fat ratios of about 1 to 1 in grams. For the most part they were weighed. Roughly three fourths of the patients were faithful to their diets. Two or 3 were exceedingly careless. Distribution of food into meals was planned according to individual tastes and habits. Most often the meals were approximately equal. A lunch at bedtime usually had been included by patients using larger amounts of protamine zinc insulin.

Previous Control.—Only 3 of the group of 60 had been able to avoid glycosuria with these orthodox methods of management. In half of them glycosuria had been intermittently excessive. Sixty per cent of the group had had frequent or severe

Chart 2—Comparison of action of 2 to 1 modifications made with regular (amorphous) and crystalline insulin. Both modifications contained only one third of the protamine and zinc present in commercial protamine zinc insulin. The slight difference in action is probably due to inactivation of protamine by foreign protein contained in amorphous insulin. It is not of practical importance. The values obtained in 3 cases are averaged in the lowest curves in terms of percentage of control values without insulin. Peak action at eight to sixteen hours with waning but not exhausted action at twenty-four hours were shown in all cases. These qualities are characteristic of this modification and were the basis for its selection for therapeutic trial.

¹⁴ Peck, F. B. Personal communication to the authors

hypoglycemic symptoms on routine management, often while asleep

In the majority of cases this tendency to intermittent glycosuria or hypoglycemia was striking enough to lead to dissatisfaction with standard methods of control on the part of patient and physician alike Fully two thirds of the patients

for insulin in solution After standing, even when buffered to pH 7.2, there is little increase in supernatant insulin This is surprising in view of the fact that precipitated insulin redissolves on buffering to this point This property will be the subject of a subsequent report It suggests the probability of a compound which does not depend on a component of simple precipitated insulin for its accelerated effect when prepared under the conditions described

Adjustment of the diabetes on the modified insulin was accomplished under quantitative conditions in the Evanston Hospital in most cases Simple substitution of the modified insulin for previous therapy did not as a rule lead to major fluctuation in control As with commercial protamine zinc insulin, its substitution for soluble insulin previously used alone tended to permit glycosuria for a day or two unless soluble insulin was tapered off

In all cases the bedtime feeding previously used with protamine zinc insulin was omitted and a midafternoon feeding added Minor adjustments of the size of the meals frequently were necessary, usually in the form of increased noon or evening meals and reduced breakfasts Such changes in the detail of the diets, along with adjustments in the size of the dose, usually compensated for individual variations in response to this modification in a single morning dose More difficulty was anticipated than was experienced from this source In 3 instances better control was obtained with two doses daily, the smaller at bedtime

RESULTS

Except for 1 child in whom a respiratory infection developed at the time of transfer, control in all patients was at least as good and usually better with the modification compared with previous standard therapeutic methods On account of the size of the group, individual quantitative data cannot be presented It was available for appraisal and was analyzed in the following manner On the basis of a 4 plus maximum each patient was judged from three standpoints, viz, average amount of glycosuria, frequency and severity of insulin shock and irregularity of control Appraisal of these indexes of control was intentionally conservative Chart 3 presents such qualitative data and the dosages used, contrasting the results of the orthodox method with those of the improved methods The accompanying table summarizes the data

Comparison of Control Obtained with Usual and Modified Methods of Insulin Dosage in Group of Sixty Diabetic Patients

	Number of Patients Showing Defects of Control			Average Insulin Dose Units
	Glycosuria	Insulin Shock	Irregularity	
Previous insulin therapy	57	39	36	5
Modified protamine zinc insulin	14	30	20	19
Corrected	35	4	7	
Improved	7*	6*	9	
Unchanged			75	50
Corrected or improved, per cent	83	87	75	

* One patient worse

Amount of Glycosuria—Only 7 of the 57 patients previously showing glycosuria failed to excrete less sugar Six patients previously unable to keep the urine sugar free without insulin shock were able to do so on a single daily dose of the improved preparation Twenty-two others showed improvement in glycosuria along with elimination of insulin shock In the majority the amount of glycosuria was substantially reduced

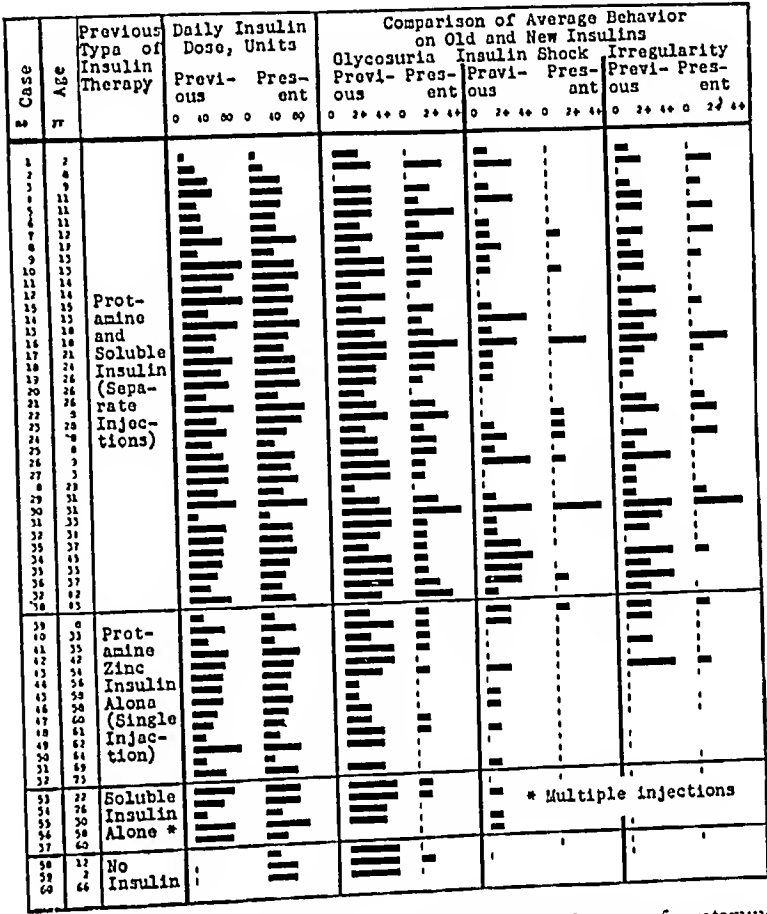

Chart 3—Results of treatment with a single modification of protamine zinc insulin, usually in one dose daily injected before breakfast Most of the 60 patients with severe diabetes showed improvement in constancy of control, glycosuria and hypoglycemic shock with the modified insulin (present) as compared with their previous experience with standard insulins, usually in multiple daily injection (previous) There was a slight reduction, on the average, in required insulin

using protamine zinc insulin exhibited this inconstant behavior For the most part, those who failed to do so had mild or early diabetes and were older

Chart 3 presents the details of the data just summarized Improved Protamine Zinc Insulin—All patients used the modifications described, which contained 2 parts of crystalline or regular insulin and 1 part of protamine zinc insulin, both in the U-80 strength All except 3 used only one dose daily before breakfast Forty-two used a 2 to 1 crystalline mixture (T-1662) mixed in quantity weeks before use and dispensed in ampules 15 Ten patients used a 2 to 1 regular mixture premixed by us in ampules from market supplies Most of the latter could also be satisfactorily adjusted with the crystalline mixture A few patients mixed insulins in the same proportions in the syringe at the time of injection No significant differences in results from these various technics were observed This modification, as shown by chart 2 and the 2 to 1 curve in chart 1, exerts its peak action at eight to sixteen hours after injection, corresponding to the hours of feeding when injected before breakfast Its effect wanes appreciably after twelve to sixteen hours, corresponding to the hours of sleep Yet a detectable effect persists into the second day For these reasons it was selected for routine use

This modification is stable at ordinary temperatures when premixed Its pH is just under 6.0, which is near the isoelectric point for insulin Its suspension is as easily rendered homogeneous by shaking as protamine zinc insulin Its crystals are indistinguishable microscopically from those of ordinary protamine zinc insulin Its supernatant activity is negligible

15 Mixed and supplied for us for clinical trial by Eli Lilly & Co

Chart 3 reflects this improvement graphically, a summary is given in the table

Hypoglycemic Symptoms—Improvement was even more striking in this respect (chart 3 and the table). Thirty patients became free from symptoms of excess insulin after adjustment on the improved modification. In only 9 did such symptoms persist when present previously, and in only 2 of these were they of such consequence as to warrant change of type of management.

Almost no nocturnal insulin shock was observed. That which occurred was mild and was easily recognized and stopped. As might be anticipated late afternoon symptoms were most common. They were avoided by increases in the size of the lunch or afternoon feeding or both. Evening symptoms were rare, even in the absence of bedtime feedings.

Irregularity of Control—Improvement in constancy of control was roughly parallel to improvement in glycosuria and hypoglycemic symptoms as described. Of 10 patients previously showing decided irregularities, only 2 continued to do so. These were exceptionally severe "brittle" young patients with diabetes of long standing who were extremely sensitive to insulin and to minor deviations in controlling factors such as exercise and timing of food and insulin. They could not be adjusted satisfactorily on any other combination of protamine zinc insulin and insulin by separate injection. Multiple injections of soluble insulin, including a small dose during the normal sleeping hours, finally produced satisfactory control in them.

Recent experience indicates that this most severe type of diabetes may be controlled even better with one of the intermediate modifications of protamine zinc insulin in two doses daily, a larger dose before breakfast and a smaller one at bedtime. Three similar cases were well controlled on such a program after single doses daily failed to cause consistently good control.

Dosage—The average dosage required by previous orthodox methods of control was 53 units daily, usually in at least two separate injections. With the modified insulin 49 units daily, on the average, was required by this group. Only 3 patients injected more than one dose daily. It is probable that several others, including the 2 failures, could have been balanced better on two doses daily.

This slight reduction in average required dosage may have been due to fresh quantitative control under hospital conditions. However, it was maintained, as a rule, on return to normal living conditions. It was frequently apparent immediately on transfer from old to new insulins, even though the diet was weighed in both cases. Any common change in feeding conditions was usually in the direction of more generous carbohydrate with the improved insulin owing to the frequent insertion of an afternoon feeding or increase in the size of the noon and evening meals in fear of insulin shock.

Judged conservatively it would seem that the 8 per cent improvement in required insulin is significant and due to greater efficiency of the modified protamine zinc insulin. This is even more impressive in view of the fact that multiple injections were avoided as a rule, glycosuria decreased and a single modification with uniform timing qualities was used in a good sized diversified group of patients with stabilized severe diabetes.

COMMENT

Integration of Time and Intensity Characteristics of Various Protamine Insulins—Analysis of the timing and intensity properties of the series of variable insulins illustrated in chart 1 demonstrates certain clearcut qualities of each. From the extremes of ordinary insulin at one end of the series to protamine zinc insulin at the other each preparation shows differences in four major qualities of action viz, promptness, intensity, duration and uniformity of effect of repeated identical doses. These four qualities bear a constant relationship in each of the different insulins in the series. Other tested intermediate preparations not illustrated fit accurately into the picture.

Soluble insulin acts the most briefly of any in the series. It is also the most prompt and intense in action. Observations not illustrated in this report demonstrate repeated identical doses to be the most uniform in effect¹² as would be expected in view of its greatest solubility and quickest rate of absorption. These observations are amply confirmed by clinical experience.

As more and more protamine insulin is added to ordinary insulin, the sugar reducing effect is prolonged. Correspondingly, promptness and intensity of action are successively reduced and constancy is sacrificed, as could be expected in view of the fact that solubility and hence absorption rates are decreased.

Protamine zinc insulin as now marketed commercially represents the other extreme, exhibiting the greatest duration of action of the series. Likewise it possesses the qualities of least promptness and intensity and greatest inconstancy of action of repeated doses of the same size, because of greatest insolubility and slowest rate of absorption. Herein lie its chief disadvantages for routine clinical use. Its action is so slow, weak, prolonged and inconstant from dose to dose that glycosuria tends to appear during food absorption and hypoglycemia during fasting, and inconsistent or undulating control tends to follow inconstant absorption of repeated overlapping doses. These characteristics, like those of soluble insulin, are also confirmed by ordinary clinical experience.

The Ideal Combination of Timing and Intensity Qualities—In the light of these practical pharmacologic properties of such a series of insulins, it is possible to specify which of them should be the ideal preparation for routine daily use. On purely theoretical grounds the ideal insulin is one whose solubility and hence rate of insulin release is such that it acts promptly and intensely enough to control the glycosuria following meals but does not cause hypoglycemia between meals. In order to avoid injections more often than once a day it must act long enough to control overnight hyperglycemia but also wane rapidly enough to avoid nocturnal hypoglycemia. It should possess the greatest possible constancy of action from dose to dose without sacrificing suitable prolongation of effect.

By these standards protamine zinc insulin as now prepared commercially acts unnecessarily long, thereby sacrificing desirable promptness, intensity and uniform absorption capacity. These qualities appear to explain its faults making it necessary to give supplementary soluble insulin for partial correction of them.

The modification used in the present study corrects those faults automatically by more efficient timing. Its rate of insulin release is such that its strongest effect, when injected before breakfast, covers the feeding period of the day and its waning effect coincides with

fasting during sleep. Yet at twenty-four hours it is still sufficiently active in most cases to avoid the necessity of more than one injection daily. Because of these intermediate properties it is more constant in action on repeated injection than protamine zinc insulin, although not as much as soluble insulin. Thus it retains the advantages of each extreme of the series, largely eliminating the disadvantages of each. It is undoubtedly for these reasons that it permits better control than commercial protamine zinc insulin.

One might object that these considerations may hold true for any given type of diabetes but that sensitivity to insulin varies so widely in different diabetic patients that preconceived properties such as those outlined cannot be fixed arbitrarily. This, in fact, was our expectation when we attempted treatment with a single preparation in a group of patients selected at random. One preparation was used in the hope of realizing simplicity as well as to test the feasibility of treating all patients alike.

We were surprised to discover that the responses were not variable enough to lead to major difficulties in this group of 60 patients representing practically all grades of severity among insulin treated subjects. Better control of almost all patients was established easily with only minor adjustments of the dosage and diet. No variation of the mixture was necessary or even desirable. In only 5 cases of the most severe and "brittle" type adjustment could not be satisfactorily made on a single daily dose of this preparation. They were equally unmanageable on any other combination of protamine zinc insulin and insulin. In 3 of them good balance was obtained with multiple injections of soluble insulin, including 1 during the hours of sleep, proving their inconsistencies due to defects of timing of depot insulins in general rather than to endogenous factors. Three of the 5 difficult cases recently have been satisfactorily balanced on two doses daily of the improved protamine zinc insulin. It seems probable that other similar cases might respond to this variation. If so, another advantage of this modified insulin would be demonstrated.

Extemporaneous Mixtures—Granting the clinical usefulness of insulins with intermediate timing and intensity qualities, Peck¹⁶ has suggested the expedient of their extemporaneous preparation by mixing in the syringe at the time of injection. In this manner, standard insulins now on the market can be mixed by the patient in the proportions best suited to his particular diabetes. Growing familiarity with the action of mixtures makes this technic fairly common practice among clinicians. Peck has prepared an ingenious table showing the approximate components of ordinary and protamine zinc insulin thought to be contained in such extemporaneous mixtures prepared with various proportions of standard insulins.¹⁶

There are several valid objections to this technic. First, many patients find it technically difficult to prepare such mixtures in the syringe.¹⁷ They are confused by the use of two insulins with different properties forming another which differs from both. Second, inaccuracies of measurement in a syringe are inevitable. Third, slight variations in excess protamine in protamine zinc insulin of different strengths prepared by different manufacturers would produce major variations

in time-intensity effect of comparable mixtures. Finally, a single intermediate preparation apparently satisfies the requirements of the vast majority of diabetic patients and in two daily doses may satisfy all, as just reported. Individualization may be accomplished easily by means of adjustments of the diet and frequency and dosage of a single modification which most nearly satisfies the requirements of the largest number of patients.

SUMMARY

1 Protamine zinc insulin as now prepared commercially possesses inherent faults of timing, owing to slow or uncertain release of insulin from its injection depots. These are seen in diabetic practice as tendencies to glycosuria following meals, to hypoglycemia during fasting, especially at night, and as unpredictable undulations in insulin intensity. For these reasons it is frequently necessary to supplement its action by separate injection of soluble insulin, and even then those tendencies are only partially avoided.

2 The timing and intensity properties of the ideal insulin for routine daily use were analyzed. A modification containing about one third of the protamine and zinc contained in commercial protamine zinc insulin fulfils those requirements most satisfactorily. In actual practice it eliminates the faults of protamine zinc insulin to a large extent. This modification may be prepared from insulins now on the market by mixing 2 parts of soluble insulin with 1 part of protamine zinc insulin, both in the U-80 strength. The time of mixing does not affect the action appreciably. It is stable for months. Slightly more intense action is obtained from mixtures made with regular insulin than with crystalline insulin, probably because of the inert protein content of the former.

3 In most diabetic patients protamine zinc insulin modified in this manner releases insulin from morning depots at a rate which causes moderate increases in intensity when needed during hours of feeding. It also allows decreases when desirable during the hours of sleeping. Therefore better control is obtained with single injections daily than with standard insulins injected more often. Occasional insulin sensitive patients obtain better control with two doses daily, the smaller at bedtime. Successive identical doses are more constant in action than with protamine zinc insulin because of accelerated solubility. Required daily dosage is about 10 per cent less than with ordinary methods because of improved efficiency.

Modification of protamine zinc insulin in this manner results in an insulin which retains all the advantages of protamine zinc insulin and eliminates many of its inadequacies.

636 Church Street

Principal Drugs of Addiction—The principal drugs of addiction are opium and its derivatives, morphine and heroin, alcohol, cannabis and cocaine. To this group may be added the barbiturates, paraldehyde, chloral and other depressants, all of which in large dosage over a long period of time may in some persons produce addiction. Of lesser power to cause addiction (or habituation) are such commonly used drugs as nicotine (tobacco), caffeine (coffee, tea, cola drinks), aspirin, acetanilid and bromides. There are, however, a host of compounds and mixtures, many of them proprietary, which are used repeatedly and habitually—Kraus, Samuel H. *The Therapy of the Neuroses and Psychoses*, Philadelphia, Lea & Febiger, 1943.

CHROMOMYCOSIS (CHROMO-
BLASTOMYCOSIS)

REPORT OF TWO CASES

MORRIS MOORE, PH D

ZOLA K COOPER, PH D

AND

RICHARD S WEISS, MD

ST LOUIS

Chromomycosis (chromoblastomycosis), or dermatitis verrucosa, presents a confusing picture at times and consequently a diagnostic problem. The clinical similarity of this disease to syphilis, tuberculosis, neoplasms and other specific and nonspecific granulomas is well known. Although considered to be a disease of the extremities presenting a nodular verrucoid papular or granulomatous appearance, reports have shown that the face, neck, chest, shoulders and buttocks also may be affected. Two cases are reported here first because of the varied diagnostic possibilities that they presented and second because of the unusual location of the lesion in 1—the helix of the ear. *Phialophora verrucosa* was isolated from the first case which was of several years' duration. Owing to the smallness of the infected area on the ear in the second case and because of a clinical diagnosis of carcinoma the whole lesion was removed and placed in a fixative. Consequently the organism could not be isolated.

REPORT OF CASES

CASE 1—History—C A C, a white man aged 30 born in Salem Mo, presented himself in May 1942 at the skin clinic of the Barnard Free Skin and Cancer Hospital complaining of an eruption on the wrist. The patient's family history and past history were irrelevant. His illness had its beginning five years previously as a small wart which had gradually increased in size, slightly more rapidly over the past two years. There had been some pruritus for the past six months. No treatment had been attempted, although he had consulted several local physicians. These physicians had referred to the condition as 'due to nerves'. At the time the lesion developed, he had been working as a farmer. For the past five years he had been working as a pipe fitter.

Examination—On admission the patient appeared to be well developed and well nourished. He was of small build weighing 125 pounds (57 Kg) and measuring 5 feet 5 inches (165 cm) in height. He was cooperative and intelligent. The ocular and general reflexes were normal. The ears, nose, abdomen, genitalia and extremities were normal. In the right flank he had a well healed scar measuring 8 cm. His teeth were dirty and covered with tartar. There was some pyorrhea with receding of the gums. The tonsils were atrophic. The lungs were clear to percussion and auscultation. The heart tones were equal regular and without murmurs. The blood pressure was 124 systolic and 86 diastolic.

On the external surface of the left forearm just above the wrist was a circinate broken plaque 2.5 cm in diameter infiltrated and having a depressed atrophic scar in the center (fig 1). The elevated granulomatous lesion was a reddish pink and had a slightly scaly surface. The diagnoses considered were tuberculosis, verrucosa cutis, syphilis, granuloma annulare and porokeratosis.

Laboratory Examination—Urinalysis was negative. The Kahn reaction was negative. The blood showed 4,890,000 red blood cells, 5,700 white blood cells and 96 per cent hemoglobin. There were 72 polymorphonuclear neutrophils, 26 lymphocytes and 2 mononuclears per hundred white cells.

Studies, observations and reports from the Department of Dermatology, Laboratory for Mycology and Department of Pathology, of the Barnard Free Skin and Cancer Hospital, service of M F Engman, Sr MD.

Microscopically sections of a biopsy specimen showed epithelial hyperplasia, hyperkeratosis and acanthosis with distortion and fusion of the rete pegs. In the upper half of the dermis there was a dense infiltrate made up of lymphocytes, epithelioid cells and many giant cells. In places the epithelioid cells were arranged in nests surrounded by lymphocytes presenting a picture which was suggestive of tubercle formation. Scattered throughout the infiltrate and within some of the giant cells however there were numerous, large dark brown, thick walled, spherical or irregular organisms. Some occurred singly, others in clumps. These were the characteristic fungi of chromomycosis.

Because of the difficulty in expressing any material from the lesion a large section of the growth was excised for the purpose of taking a culture. Approximately two thirds of the remaining lesion was removed. This was cut up into small pieces and planted on Czapek's and Sabouraud's dextrose and maltose agar. After four days small black colonies appeared.

Fig 1 (case 1)—Verrucous chromomycosis of the wrist of five years duration.

on and around the implanted tissue. The fungus was identified as *Phialophora verrucosa*.

CASE 2—History—C E D, a white man aged 38, a farmer who had been born and had continuously lived in Missouri, presented himself in May 1942 at the Barnard Free Skin and Cancer Hospital complaining of a 'sore' on the right ear. He was assigned to the surgical clinic by the admitting officer. The family history was irrelevant. His past history was essentially negative and did not relate to his complaint on admission. On physical examination his respiratory, cardiovascular and gastrointestinal systems were normal. His present illness had begun two months before at which time he noticed an eruption on the helix of his right ear. This had slowly increased in size.

Examination—Just inside the helix of the right ear there was a slightly raised ulcerative area measuring 1.5 by 0.6 cm. There were no palpable nodes in the neck. The clinical diagnosis was squamous cell carcinoma. An excision of the entire lesion and part of the cartilage was recommended. On June 1, 1942, a cautery excision of the lesion including a segment of the cartilage, was made.

Laboratory Examination—The surgical specimen consisted of an ellipse of skin measuring 25 by 15 cm. It showed a nodular, crusted lesion which on section appeared to be woody hard. The process did not involve the underlying cartilage.

Microscopically, a section of the tissue showed epidermal hyperplasia, extensive hyperkeratosis, parakeratosis and acanthosis with a lengthening and distortion of the rete pegs. Extending throughout the upper two thirds of the dermis was an extensive infiltrate made up of lymphocytes, eosinophils, polymorphonuclear leukocytes and numerous giant cells. In the giant cells and also scattered throughout the infiltrate were numerous brown, thick walled organisms. In some of the organisms cross walls could be seen. These were the characteristic organisms of chromomycosis.

HISTORY OF THE DISEASE

The discovery of chromomycosis is attributed to Pedroso, who in 1911 described the first case from Brazil. He called it "black blastomycosis" because of

Fig 2 (case 1)—Section through lesion. Note acanthosis and infiltrate in corium, with giant cell formation. Hematoxylin and eosin stain, reduced from a photomicrograph with a magnification of 145 diameters.

the finding of dark brown cells in the sections of the diseased tissue. In 1920 Pedroso and Gomes¹ published a report of this case with 3 others from Brazil. The organism of each case was named *Phialophora verrucosa* on the basis of the organism described by Thaxter from the first case reported in the United States in 1915 by Lane² and Medlar³.

Since 1920, numerous cases of chromomycosis have been reported throughout the world. These have been

reviewed by de Almeida,⁴ Moore and Mapother⁵ and recently by Weidman and Rosenthal.⁶ The last named authors compiled a great deal of the known data on the published cases, listing them as to geographic and anatomic distribution. Of special interest since the review of Weidman and Rosenthal is the publication of Pardo-Castello, Leon and Trespalacios⁷ in which 31 cases were reported not only on the extremities but also on the chest, buttock and shoulder.

In spite of the large number of cases reported, including the 2 described here, only 6 have been shown to be due to *Phialophora*. Of these a Brazilian case was due to *Phialophora macrospora* and the 5 others were caused by *P. verrucosa*. In 1915 Lane and also Medlar reported the first case of chromomycosis caused by *P. verrucosa*, the organism being established taxonomically by Thaxter with a new generic and species determination. The patient was an Italian aged 19 living in the environs of Boston. The organism was isolated from verrucous, nodular lesions on the buttock.

In 1920 Pedroso and Gomes published reports of their 4 cases gathered over a period of several years. Of these 4 cases the 1 described by Pedroso in 1911 showed extensive scarring—the syphilitic type of Pardo-Castello, Leon and Trespalacios—plus verrucous areas, the second showed verrucous, papillomatous lesions with perhaps autoinoculation on the neck, the third showed involvement of the foot with a verrucous patch on the heel, and the fourth showed an extensive involvement of the foot with the lesion extending above the knee to produce the verrucous type with elephantiasis. An organism isolated from one of these cases was shown to be *P. macrospora* by Moore and de Almeida.⁸

In 1933 Wilson, Hulsey and Weidman⁹ described a lesion on the right foot of a 67 year old farmer from Fort Worth, Texas. The lesion had shown a development from a papular to a nodular and verrucous stage with some elephantiasis. The organism isolated from this case was *P. verrucosa*. In the following year MacKinnon¹⁰ described a case from Montevideo, Uruguay, due to *P. verrucosa*. The lesion was papular and papillomatous and was located in the region of the anatomic snuffbox of the right hand.

The report of the fourth case in the United States was published by Moore and Mapother. The lesion was crusted, raised and ulcerating, with a pearly border and was located on the right side of the face of a man aged 67. The fungus isolated was *P. verrucosa*.

The fifth case caused by *P. verrucosa* and the sixth caused by the genus are described in this paper.

The number of cases occurring in continental United States, with reports published and unpublished, now totals 9. These are listed in the accompanying table.

DESCRIPTION OF ORGANISM

Owing to the fact that a clinical diagnosis of squamous cell carcinoma was made in the second case and the lesion completely excised and placed in a fixative it was impossible to obtain any cultures. Cultures from the first case, however, were obtained by seeding tubes of medium with finely cut up tissue obtained by biopsy.

Fig. 3 (case 1)—Brown thick walled cells of *Phialophora verrucosa* in giant cells. Hematoxylin and eosin stain reduced from a photomicrograph with a magnification of 710 diameters.

The organism when seen in tissue consists of spherical or irregular sclerotic cells which are thick walled dark brown or chestnut colored and simple or multiple appearing in clusters. The cells reproduce by enlargement and septum formation to produce the mulberry-like groups. Budding of these fungi is not a characteristic form of reproduction in tissue. These cells may be seen distributed throughout the affected tissue, in microabscesses surrounded by polymorphonuclear

Fig. 4 (case 2)—Section through ear lesion. Note thickening of tissue due to hyperplasia with acanthosis. Hematoxylin and eosin stain reduced from a photomicrograph with a magnification of 10 diameters.

leukocytes or engulfed by giant cells. In old lesions or necrotic tissue the cells may occasionally germinate to produce short filaments.

Tissue implants on Czapek's and Sabouraud's dextrose and maltose mediums resulted in small black colonies which appeared after four days on and around the inoculum. When the colonies developed to a suitable size, subcultures were made on various mediums.

The organism microscopically was identified as *Phialophora verrucosa*.

The growth of *P. verrucosa* on artificial mediums both macroscopically and microscopically has been well described. The strain isolated here is essentially similar microscopically to the strains isolated from Boston, Fort Worth, Montevideo and St. Louis.

In culture the thick walled brown cells germinate to form multiseptate hyphae. These vary in form and size from 2 to 5 microns in diameter depending on the medium on which the fungus is growing. As the organism grows it forms various morphologic structures which are modified by the ingredients of the medium. The hyphae are seen as multiseptate filaments occurring singly or in bunches (coremoid) simple or somewhat branched. The cells are either elongated or short. The latter may be seen also in chains as spherical cells, moniliform in appearance. This type of cell formation is characteristically found growing in all mediums but

Fig. 5 (case 2)—Section through ear lesion showing protuberant cellular infiltrate with organisms, giant cells and many leukocytes. Hematoxylin and eosin stain reduced from a photomicrograph with a magnification of 145 diameters.

is a prominent feature on sugar mediums. Chlamydospores may also be seen. These either occur terminally or may be found intercalary. They are thick walled, large and spherical and simulate those seen in the infected tissue. On certain mediums, such as Loeffler's agar, these cells assume a close similarity to the sclerotic forms seen in sections of diseased tissue.

The reproductive organs of *P. verrucosa* the phialides—cuplike structures with endogenous spore formation—develop in most mediums but are most prevalent on synthetic mediums such as Czapek's agar (fig. 7). These spore bearing structures develop terminally laterally or alternately on a hyphae are single or many celled simple or branched short or long. The spores or conidia arise endogenously and are expelled from the cuplike portion of the phialide. They collect at the

mouth of the phialide in a group and are held together by a mucilaginous material termed gloea. The phialospores or conidia are at first small, spherical to ovoid cells and then become elongated or fusiform to measure approximately 1 to 3 by 2 to 4 microns. These spores germinate to reproduce the structures noted.

Grossly, after fifteen days, growth on Czapek's agar P verrucosa attained a colony size of 3.5 cm in diameter (1, fig 8). A central button was formed with the mycelium both aerial and subsurface. The color varied from an olivaceous brown to blue-black. On corn meal agar, after the same period of growth, the colony reached a diameter of 3.2 cm (2, fig 8). A central button with sector formation was produced. The color was dark gray to black. On the peptone agar growth was comparatively slow, with a diameter of 1.5 cm after fifteen days (3, fig 8). The colony was compact and showed aerial mycelium which was a dark gray, but the compact portion of the growth was black. On Sabouraud's medium, both dextrose and maltose, the growth was essentially similar. The colony on the dextrose medium reached a diameter of 2.8 cm

may occur on almost all parts of the human skin. These include, in addition to the hands and feet, the wrist, arm, shoulder, neck, face, ear, chest, abdominal region, thigh, knee and leg. However, the greater number of cases show the lesions on the extremities. The reason for this is that the primary lesion in many instances has apparently been the result of a traumatic infection with contaminated material. The larger number of patients were farmers, workers of the soil or its products. This has certainly been true of the 3 patients observed in St. Louis.

Clinically, chromomycosis presents lesions which may be papular, verrucous or papillomatous, nodular, ulcerative, psoriasiform, granulomatous, with or without abscess formation and with rarely any suppuration except when due to secondary infection with bacteria. Scaliness is often a feature. Pain or pruritus rarely occurs. Visceral or skin metastases have been reported only in 2 cases, 1 from Algeria¹¹ and one from Puerto Rico¹². Systemic invasion is not a feature of chromomycosis. Bone involvement likewise has not been reported. Lymphangitis and adenopathy (regional)

(5, fig 8), while on the maltose agar it was 2.5 cm (4, fig 8). The cultures were sharply defined with some aerial growth. The color was slate gray to black. The growth on potato-dextrose agar measured 3 cm in diameter after fifteen days (6, fig 8). The colony showed a central knob with evidence of slight concentric growth. The color varied from light to dark olivaceous gray.

CLINICAL FEATURES

Chromomycosis clinically is seldom recognized except perhaps in areas in which the disease flourishes and presents characteristic verrucous lesions on the extremities. With the exception of these typical cases, the disease has perhaps never been diagnosed clinically. The first indication of the correct determination has come from the pathologist, who found the sclerotic, dark brown, thick walled cells in the tissue section. Like blastomycosis, coccidioidomycosis, syphilis and neoplasms, this relatively recently recognized disease, chromomycosis, presents a number of gross clinical features which may be confusing and misleading.

Chromomycosis has generally been considered to be a disease of the extremities. Recent reports, including the 2 cases presented in this paper, indicate that lesions

may occur but are usually attributed to secondary infection. As the disease progresses and persists, there is cicatrization such as is found in blastomycosis. On the extremities the progressive formation of additional lesions accompanied by tissue reaction may result in elephantiasis. The enlargement of the foot in these cases resembles Madura foot.

On the basis of the reports in the literature and on their series of 31 cases, Pardo-Castello and his associates classified chromomycosis into five clinical types: 1. The verrucous or papillomatous type, which begins as a group of small nodules or papules with a scaly surface. These nodules increase in size and usually form large circular masses which tend to heal in the center with scar formation. Abscesses may be found in the area of granulation tissue, but suppuration does not result. The appearance is not unlike that of blastomycosis or tuberculosis verrucosa cutis. Case 1 is a good example of this most common type. 2. The tuberculoid type, which is in all probability an early

11 Montpelier, J. and Catanei, A. Mycose humaine due à un champignon du genre Hormodendron H. algeriensis, nov. sp. Ann. de dermat. et syph. 8: 627 (Nov.) 1927.

form of verrucous chromomycosis also resembles tuberculosis verrucosa cutis or sarcoid. The lesions begin as small patches or nodules with erythematous areolas and little scaling. 3 The syphiloid form which is nodular and scaly, with some erythema. The nodules are small, flattened and serpiginous, annular or arcuate

Fig 6 (case 2)—Section through ear lesion showing brown thick walled cells of the organism and many polymorphonuclear leukocytes. Hematoxylin and eosin stain reduced from a photomicrograph with a magnification of 910 diameters.

in their arrangement. The lesions may resemble a superficial late syphiloderm. Ulceration with a hypertrophic base may be present due to granulation tissue. The surface may be covered with crusts. 4 The psoriasiform type, which consists of superficial inflammation and infiltration with the lesion covered with thick white adherent scales. Abscesses and verrucous patches are not observed and the lesion resembles psoriasis. 5 The fifth group, which is made up of those lesions which become cicatrized and those which result in the elephantiasic enlargement of the extremities. This group no doubt represents an end result or an advanced stage of chromomycosis, since scarring is found in lesions of long duration and swelling of the affected areas does occur when there is a multiplicity of lesions. The usual features of verrucosities, abscesses, ulceration and scaling may be present. The resemblance to Madura foot has been noted previously.

It would seem therefore that because of the varied appearance of the lesion, chromomycosis should be differentiated clinically from various mycotic granulomas, including coccidioidal granuloma, blastomycosis and maduromycosis or Madura foot, from tuberculosis verrucosa cutis, syphilis, epithelioma, psoriasis, leishmaniasis¹³ and, as discussed by Carini,¹⁴ from sarcoid, pyoderma vegetans, yaws, porokeratosis, granuloma annulare, mossy foot and no doubt other clinical entities.

MICROSCOPIC OBSERVATIONS

A clinical diagnosis has seldom been made except in the case of typical lesions. The task of determining the cause of the infection has invariably fallen to the microscopist. The diagnosis is readily made by finding the characteristic fungous cells in the diseased tissue.

Microscopically, the lesions of chromomycosis show a number of features which are compatible with the

general picture seen in sections of blastomycosis, tuberculosis and other mycotic granulomas. There are, however, certain characteristics which may serve to differentiate the disease.

The epidermis shows hyperkeratosis and acanthosis with a thickening, broadening and elongation of the rete pegs. Within these pegs may be seen microscopic abscesses filled with polymorphonuclear leukocytes, cellular debris and the fungous cells. At times within these areas one may also find Langhans giant cells containing fungi.

The most pronounced changes are found in the dermis. Here one sees edema, a pronounced cellular infiltration and, in older lesions, evidence of fibrosis. The cellular infiltration is made up of polymorphonuclear leukocytes, lymphocytes, epithelioid cells, plasma cells, eosinophils and Russell's fuchsin bodies, which have been noted in tissue sections by others. Giant cells of the foreign body or Langhans type may be present as well as macrophages. There is sometimes a tendency to pseudotubercle formation in the infiltrate. Fibroblastic changes may occur. Necrosis and microabscesses such as are found in Gilchrist's disease are not prominent in chromomycosis. The sclerotic cells of the fungus are found scattered throughout the corium, especially in the abscesses or in giant cells. They occur either as single cells or in mulberry-like clusters.

A comparison of our 2 cases of chromomycosis is of interest. The first case, of five years' duration, presented a clinical picture which could easily have been mistaken for tuberculosis verrucosa cutis or syphilis (fig 1). Microscopically the picture presents the characteristics seen in typical chromomycosis (fig 2). Characteristically tubercle-like formation is seen. Distributed through these cellular masses, both free and in giant cells, are the fungous cells of *P. verrucosa* (fig 3).

In the second case, apparently of two months' duration, the physical examination revealed a slightly ulcer-

Fig 7—Six days growth of *Phialophora verrucosa* on Czapek's agar (subculture). Note phialides groups of spores and moniloid formation. Reduced from a photomicrograph with a magnification of 1160 diameters.

ated lesion somewhat infiltrated. The clinical diagnosis of squamous cell carcinoma indicates clearly the diagnostic difficulties. Microscopically, the section of tissue shows thickening and edema with hyperplasia, hyperkeratosis and acanthosis (fig 4). This lesion, representing an early infection, shows also the extensive infiltration with the various types of cells so noticeable

13 Terra F, Torres M, da Fonseca O, and Area Leao A. E. Novo tipo de dermatite verrucosa mycose por *Acrotheca* com associação de leishmaniose. *Brasil med* 2: 363 (Dec 9) 1922.
14 Carini A. Sur la dermatite verrucuse. *Bull Soc. path. exot.* 17: 227 (March) 1924.

in chromomycosis. Here, however, the granulomatous changes are not particularly prominent. Instead, there is seen a general infiltration of many types of cells, including some giant cells (fig 5). Fibrosis, so apparent in older, chronic lesions, is absent. Edema with consequent swelling is evident. Dispersed throughout this rich cellular infiltrate, of which the greater number of cells are polymorphonuclear leukocytes, are seen the sclerotic cells of the fungus (fig 6).

PROGNOSIS AND TREATMENT

Chromomycosis is not a fatal disease. It is a disease of slow evolution, as has been pointed out. The prognosis is good unless there is a secondary complica-

Mapother's patient showed good results with a rapid clearing of the lesion following the use of iodides by mouth. On the other hand, Pardo-Castello and his co-workers found no improvement in the majority of their cases after the administration of iodides by mouth or intravenously. Roentgen irradiation may be of great value in localized patches of chromomycosis. In the unpublished case of Sams, potassium iodide was given by mouth, 30 grains (2 Gm) three times a day, and filtered roentgen rays subintensively, 225 roentgens for four months at monthly intervals. The lesion responded very well, leaving a thin scar.

Pardo-Castello and his associates used intensive ray therapy, 600 to 1,200 roentgens filtered through 1 or 2 mm of aluminum, depending on the thickness of the lesion, with benefit. If the lesions are not too extensive, cauterization, electrocoagulation or surgical excision may be successfully employed. In 1 of our 2 cases surgical excision and complete removal of the lesion brought about an apparent cure.

The use of thymol internally, 1 Gm daily before breakfast, has been of no value. The various organic salts of antimony and copper, colloidal copper intravenously and the sulfonamide group of drugs were of no benefit in the cases in which these were tried by Pardo-Castello.

When the lesion is small, therefore, the treatment may be either iodides and roentgen radiation, electrocoagulation or surgical excision. When the lesion is extensive, it is a matter of experimentation. If the lesion results in elephantiasis of the extremity, perhaps the only recourse lies in amputation.

COMMENT

Chromomycosis is rapidly assuming a place of importance in dermatology. The discovery of many cases in the past few years does not necessarily mean that the incidence of the disease has become higher. Certainly in cases in which biopsy was not done routinely the clinical diagnoses of tuberculosis verrucosa cutis, blastomycosis or the various other previously mentioned entities could have been made. It may be that closer attention is now being paid to the microscopic and clinical features of chromomycosis by clinicians who have become better acquainted with the disease.

There are several additional features of chromomycosis which have not been mentioned but should receive just a few words in passing. In the first place, the disease is practically universal in its geographic distribution. Reports of chromomycosis have come from North, Central and South America, the West Indies, Europe, Asia and Africa. It is not entirely a disease of the tropics, as was first thought. Two cases from Canada have recently come to the attention of one of us (Moore).

Chromomycosis occurs chiefly among farmers or those associated with farm produce. There have been some exceptions, but a careful search into the history of the particular patient has invariably disclosed some association with vegetation. The 2 cases presented here were no exceptions.

Age is not a causative factor in this disease. The patients have varied considerably in their ages. Dr Almeida listed 54 cases, of which 43 occurred between the ages of 10 and 80, the ages in the other 11 cases were not classified. Pardo-Castello and his associates found that the ages in their 31 cases varied from 14 to 70. Most of the lesions have occurred in the age

Fig 8—*Phialophora verrucosa*. Actual size after fifteen days' growth. 1 Czapek's agar 2 Corn meal agar 3 Peptone agar 4 Sabouraud's maltose agar 5 Sabouraud's dextrose agar 6 Potato dextrose agar

tion of tuberculosis, leishmaniasis, as in the case of Terra, Torres, da Fonseca and Arêa Leão, or some other fatal disease. Scar formation may result in loss of use of the affected limb, if the scarring is severe enough to cause retraction of the tissue. In the elephantiasis type of lesion there may result loss of use of the limb, either temporary or permanent, because of the excess weight and because of stiffening of the joints.

Therapy for chromomycosis has not been encouraging in most cases. Iodides by mouth or intravenously have not met with success in all cases. Usually this form of therapy has been supplemented with roentgen irradiation. In such instances it is difficult to evaluate the therapeutic agents individually. Moore and

range of 30 to 50 years. The disease is found chiefly among males, with only 4 reported among females.¹⁵ The worldwide distribution of the disease indicates that all races and nationalities may be susceptible.

Chromomycosis has a slow evolution. Many of the cases reported by Pardo-Castello and his co-workers had a duration of twenty to twenty-five years. Wilson Hulsev and Weidman's case had a duration of forty years.

It is agreed by all observers of the disease that it is not truly a blastomycosis. This has been emphasized in published articles stressing the fact that the fungus either in tissue or in culture does not bud but divides by cross wall or septum formation. The term chromoblastomycosis, as originally described by Terra Torres da Fonseca and Arca Leão was therefore revised by Moore and de Almeida² to chromomycosis. This name, besides being shorter, eliminates the possibility of confusing the disease with blastomycosis. The objection raised to retaining the term chromomycosis is that it may be confused with chromophytosis (pityriasis or tinea versicolor). However, "chromophytosis" is rarely used and should not, therefore cause any concern to dermatologists, since they prefer the term pityriasis (tinea) versicolor. It is obvious that unless the term chromoblastomycosis is abandoned the confusion of this disease with blastomycosis must be expected.

SUMMARY AND CONCLUSIONS

The 2 cases of chromomycosis presented are the eighth and ninth cases respectively occurring in continental United States. One was of five years duration and was caused by *Phialophora verrucosa*. This represents the sixth case due to the genus *Phialophora* and the fifth caused by *P. verrucosa*.

The lesion in the first case occurred on the left wrist, was verrucous and granulomatous and was difficult to differentiate clinically from tuberculosis verrucosa cutis, syphilis, granuloma annulare, porokeratosis and blastomycosis. The microscopic features of chromomycosis in general and of this lesion in particular were examined. An analysis of the histopathologic features indicates that the infection had all the characteristics of a granulomatous lesion of chromomycosis with tubercle-like formation. The organisms were profuse in the infected tissue.

The infection in the second case was primary on the helix of the right ear and was of two months' duration. The lesion was raised and ulcerative and clinically was diagnosed squamous cell carcinoma. A cautery excision of the lesion was done. Since the excised tissue was placed in a fixative, the causative agent could not be cultured. Microscopically, the section of tissue showed features characteristic of chromomycosis. However, instead of the granulomatous tissue changes so noticeable in the sections of the first case, an infiltration of various types of cells, chiefly polymorphonuclear leukocytes, was present. Dispersed throughout this infiltrate were many fungous cells.

The organism is similar microscopically to other strains isolated at Boston, Fort Worth, Montevideo and St Louis.

METABOLIC STUDIES IN PATIENTS WITH CANCER OF THE GASTRO- INTESTINAL TRACT

PANCREATIC INSUFFICIENCY IN A PATIENT TREATED SURGICALLY FOR CARCINOMA OF THE AMPULLA OF VATER

P. E. REKERS, MD

GEORGE T. PACK, MD

C. P. RHOADS, MD
NEW YORK

The exclusion of the pancreatic juice from the intestine resultant to resection of the duodenum or of the head of the pancreas frequently is followed by a disorder marked by an increase in the quantity of nitrogen, fat and starch eliminated in the feces.¹ Whereas it would be supposed that the disorder could be controlled by the administration of pancreatic secretions, the results of the small numbers of reported studies of the procedure are not uniform.

A patient has been studied who had undergone a resection of the duodenum for carcinoma of the ampulla

TABLE 1—The Excretion of Nitrogen in the Stools and the Urine and the Excretion of Fat in the Stools of the Patient Under Study

Days	Daily Diet			Feces				
	Fat Gm	Protein Nitrogen Gm	Calories	Fat Gm per Day	Fat, per Cent of That Ingested	Nitrogen Gm per Day	Nitrogen per Cent of That Ingested	Urinary Nitrogen Gm per Day
9	26	10.1	2,400	32.7	25	4.9	48	5.2
5	45	10.0	2,400	39.5	57.5	3.9	39	3.2

of Vater and who presented the clinical picture of pancreatic deficiency. The results of this study suggest an effective therapeutic procedure, which may be useful in the management of other cases of this type.

MATERIAL

The patient was a woman aged 39 who originally was admitted to the hospital with jaundice, acholic stools, bile in the urine and an abdominal mass. The first stage of the operation consisted of a cholecystogastrostomy. In the second stage a gastroenterostomy was made, the head of the pancreas was resected, the pancreatic ducts and the common bile duct (distal to the cystic duct) were ligated and excised, and finally the pylorus with the duodenum and ampulla of Vater was resected. During the one year interval before she was readmitted to the hospital her stools always were voluminous soft and gray but not acholic. There was a loss of weight of 15 pounds (6.8 Kg.)

Six hospitalized subjects were studied as controls. They were admitted for the treatment of disorders entirely unrelated to the gastrointestinal tract.

METHODS

The diets fed to all the subjects during the period of study contained constant, known amounts of fat, protein and carbohydrate, taken in three equal meals daily. A single source of meat was used. The protein and fat contents of the diets of the patient and of two of the controls (L. D. and A. F.) were established by analysis.³ The intakes of the other persons studied were calculated from tabulated values (tables 1 and 2). During the period of observation no gastrointestinal disorders were noted in the control subjects. The control subjects and the patient were kept on the constant intake

RESULTS

The control subjects were observed over periods which varied in length from four to seventy days. None excreted in the stool a daily average of more than 5.6 Gm. of fat or 1.5 Gm. of nitrogen (table 2). The findings in the patient were strikingly abnormal.⁴ During two separate control periods of eight and nine days (table 1) the average daily amounts of fat excreted in the feces were 39.5 and 32.7 Gm., and the average amounts of nitrogen 3.9 and 4.9 Gm. daily. Thus, from 87.5 to 95 per cent of the fat and from 39 to 48 per cent of the nitrogen ingested was lost in the feces. The excess of nitrogen excreted in the feces of the patient under study readily was demonstrated to be of dietary origin. When the diet was altered to contain only 0.2 Gm. of protein nitrogen for a period of nine

for five days before the collection of stools and urine was begun. In the course of the study certain dietary supplements were added. The methods used for the collection of stools and of urine and for the determination of stool lipid have been described in a previous publication of this series.^{3a} The stool lipid content was calculated in terms of the "stearin equivalent" and is expressed throughout this communication as "stool fat." The nitrogen in the stools and the urine was determined by means of a micro-Kjeldahl technic.^{3b}

days the output of nitrogen in the feces rapidly decreased to an average daily value of 2.2 Gm. The addition of 6 Gm. of amino acid nitrogen⁵ per day during another period of seven days did not increase significantly the fecal output. This observation indicated that the digestion of protein was impaired and not the absorption of the simple end products of protein breakdown (table 3). It was not feasible to study in a similar fashion the effects of decreasing the fat content of the diet. In view of the considerable surgical reconstruction of the patient's gastrointestinal tract, two possible causes

existed for the functional disorder the exclusion of extrinsic pancreatic secretion and the altered flow of bile into the intestine. Accordingly, 18 Gm of bile salts* was administered daily for four days, but this induced only diarrhea and greater excretion of both fat and nitrogen (table 4).

TABLE 5—The Effects of the Addition of Dietary Protein and Fat Supplements on the Excretion of Fat and Nitrogen by the Patient Under Study

* Baal.

Pancreatic enzymes were next tested. The daily ingestion of 6 Gm of lipocain, a material obtained from pancreas which has to do with certain phases of the internal metabolism of fat, was without significant effect. As a source of enzymes of the external secretions of the pancreas, 25 Gm of Pancreatins⁸ then was administered each day for six days. The daily excretion of fat in the stool fell rapidly and progressively from an average basal level of 36.1 Gm to only 13.7 Gm, or from 91 to 32 per cent of the amount ingested. Likewise the daily fecal output of nitrogen decreased progressively from an average basal level of 4.4 to 0.3 Gm, or from 44.5 per cent to 3 per cent of that ingested as protein (table 4). Associated with this striking change, the frequency, the bulk and the foul odor of the stools were reduced.

The daily dose of pancreas extract was decreased to 12 Gm per day for the next twenty days, and definite clinical improvement occurred. It was not feasible during that period to make further determinations.

During the course of this study it was possible to ascertain certain relationships between the fat and nitrogen contents of the diet and the amounts of those substances excreted. The administration of a supplement of 53 Gm of fat and 13 Gm of protein nitrogen (table 5) with the constant diet resulted in a relative decrease in the excretion of both these substances. The daily absorption of the total amount of fat increased from about 4 to 62 Gm and of nitrogen from about 5.6 to 16.5 Gm. When nitrogen intake was decreased the total amount of fat excreted increased, which suggested that at least part of the effect noted in the preceding period might have been due to the high protein content of the diet.

COMMENT

Pronounced loss of fat and nitrogen was observed in a patient whose pancreatic ducts had been ligated during resection of the head of the pancreas and duodenum. The possible causes for the excess excretion were considered to be (a) an inability to digest fat and nitrogen into those compounds which could be absorbed, (b) an inability to absorb even simple fat and nitrogen compounds or (c) an excess intestinal secretion of fat and nitrogen compounds.

Oral administration of protein split products (amino acids) did not increase the nitrogen content of the feces, and a lower protein intake was followed by a definite reduction. Hence it appears that the abnormal output of stool nitrogen, at least, is due to the inability of the patient to digest protein.

Of the therapeutic materials which seemed likely to be useful for this patient, external pancreatic enzymes were by far the best, whereas lipocain and bile salts were without effect. A regimen based on a diet composed of the easily absorbed foodstuffs, namely amino acids, fatty acids and simple monosaccharides, is not practicable. The use of a diet high in its content of fat and protein apparently did increase the patient's ability to absorb these foodstuffs, but it increased the bulk of the stools and the discomfort of the patient.

SUMMARY

A patient who had had the duodenum and the head of the pancreas resected and the pancreatic ducts ligated presented the clinical picture of pancreatic insufficiency. The administration of large quantities of pancreatic enzymes was followed by conspicuous clinical benefit and by a significant decrease in the amounts of fat and nitrogen excreted in the feces. An increase in the protein content of the diet resulted in increased absorption of fat. An increase of the fat content of the diet resulted in an increase of fat absorbed but no lessening of fat lost.

Clinical Notes, Suggestions and New Instruments

MENINGOMYELITIS

A COMPLICATION OF PRIMARY ATYPICAL PNEUMONIA

Numerous reports have appeared in the literature of the last two years pertaining to an acute pulmonary infection characterized by cough, general malaise and hyperpyrexia associated with a relative leukopenia. The mortality rate is low and the physical findings are described as minimal. Roentgenograms uniformly reveal patchy veil-like shadows involving areas of the lung much greater in area than would be suspected from the physical examination. Various names have been applied to this syndrome, such as "pneumonitis" and "virus pneumonia." More recently the descriptive title "pneumonia, primary, atypical etiology unknown" has been adopted as official nomenclature by the Medical Departments of both the Army and the Navy. A survey of the current literature indicates that complications of this increasingly prevalent pulmonary infection are few, the disease tending to run a self-limited course without sequelae. This observation is further confirmed by a review of 150 cases admitted to the Medical Division of the hospital at which we are stationed. It is our purpose in this report to describe the occurrence of an unusual and serious involvement of the central nervous system apparently developing as a direct sequel to primary atypical pneumonia.

The patient, a naval officer aged 37, was in good health until Sept. 20, 1942, when he began to complain of headache, chills and general malaise. The following day the temperature rose to 101 F and he developed a paroxysmal hacking cough productive of a moderate amount of mucopurulent sputum and frequently followed by regurgitation of food. He was ordered to bed by his physician and was treated symptomatically. He

responded well enough to be placed on light duty about one week after the onset of his illness. The second day out of bed, however, his symptoms recurred and once again he developed chills, fever and extreme weakness.

On the tenth day after onset he entered the hospital, ambulatory, and did not appear to be seriously ill. His temperature was 102 F, the pulse rate 95 per minute and respiratory rate 18 per minute. Physical examination revealed that the pharynx was injected, the nose obstructed and an inspiratory lag was present on the left side of the chest with slight impairment and decrease in breath sounds at the left base. It was noted that the reflexes were equal and active and that no Babinski reflex was present. The leukocytes numbered 11,700 with 72 per cent neutrophils, the sedimentation rate was very rapid (29 in 30 minutes), the sputum showed a few diplococci and the blood culture was sterile. X-ray examination of the chest revealed mottled and homogeneous densities in both lower lung fields, consistent with a primary, atypical pneumonia.

The patient was treated symptomatically with salicylates, gargles and ephedrine nasal spray.

The second evening in the hospital the patient's temperature rose to 104 F and he became extremely prostrated and vomited repeatedly. It was noted that the cough was incessant but the coughing effort weak and nonproductive. The bladder was found to be much distended although the patient experienced no discomfort whatever from this source. One thousand cc of urine was obtained on catheterization. There was also a temporary loss of control of the rectal sphincter.

A neurologic examination revealed that the patient was slightly irrational, his voice feeble and his cough reflex considerably diminished. His respirations were entirely abdominal with no apparent movement of the intercostal muscles. The cranial nerves were intact and the sensory system unimpaired. There was extreme motor weakness of both extremities. The knee and ankle reflexes were hyperactive on both sides. Reflexes in the upper extremities were equal and active. There were bilateral Babinski and Chaddock signs, and the abdominal and cremasteric reflexes were absent. A lumbar puncture was done at this time and a slightly cloudy fluid under pressure of 250 mm was obtained. The cell count was 221 with 87 per cent lymphocytes, total protein was 40 mg, sugar was 90.9 mg and the Kalin reaction and colloidal gold test were negative. Bacteriologic study of the fluid was negative. The patient apparently had a meningomyelitis of the lower lumbar region with patchy involvement of the spinal cord at higher levels. The findings indicated that the pathologic changes were limited to the motor system of the anterior and lateral columns of the cord, hence the absence of sensory findings. The etiologic agent was possibly blood borne via the anterior and ventral spinal arteries and their corona vasorum. The type of involvement is comparable to that noted in poliomyelitis except for the presence of hyperactive deep tendon reflexes (a sign pathognomonic of involvement of the pyramidal or corticospinal pathway in the lateral columns). The pronounced distention of the urinary bladder without subjective symptoms of discomfort and without evidence of obstruction of the lower urogenital tract could be explained only on the basis of bladder atony secondary to cord involvement.

Respiration became increasingly difficult and, in the absence of a mechanical respirator, the special watch was increased to provide personnel for continuous artificial respiration. The urinary retention was overcome by the installation of a retention catheter, and the bladder was irrigated twice daily.

In addition, repeated injections of hypertonic dextrose (25 per cent solution) were given and oxygen was administered continuously by means of the B. L. B. mask.

During the next twenty-four hour period there was definite improvement in respiration and a noticeable decrease in the signs and symptoms of general toxemia.

On the fifth hospital day the patient appeared to be greatly improved. His temperature was 100 F, respirations were normal and slight movement of his legs was noticed. Massage and passive motion were instituted to maintain tonicity and circulation of the muscles. He continued to improve gradually, and one week after admission a spinal fluid examination showed that the cell count had decreased from 221 to 41, protein from 40 to 25 mg and sugar from 90.9 mg to 64.5 mg.

Specimens of spinal fluid and blood were submitted to the Department of Infectious Diseases of the National Institute of Health. The report indicated that no recognizable virus was demonstrated by animal inoculation, although special search was made for the various neurotropic viruses, influenza A and B and Q fever.

On the eighth hospital day the retention catheter was removed and the patient gradually regained the ability to void spontaneously. At this time the paralysis of his legs began to disappear rapidly and he soon regained voluntary control of the muscles.

The deep and superficial reflexes of the trunk and lower extremities returned to normal coincidentally with the disappearance of the motor paralysis.

Except for a mild cystitis, his recovery proceeded uneventfully and he was discharged from the hospital one month after admission. After return to duty slight weakness in the legs and paresthesia of the toes were noted for a short time.

COMMENT

Myelitis is a not uncommon complication of severe infections such as syphilis, tuberculosis, typhus, diphtheria, typhoid and smallpox. The deleterious effects on the cord may be produced by direct action of the bacteria or by their toxins. During World War I and in the decade following this period a number of reports are to be found in the literature¹ which describe the occurrence of myelitis secondary to respiratory infections of various types.

In these cases the onset of the disease was marked by an upper respiratory infection, pain in the chest and severe generalized muscular pains. Later paresis developed in one or more of the extremities with pronounced reduction or abolition of the deep tendon reflexes. There were a concomitant disturbance of sphincter control and objective sensory disturbances both deep and superficial. The spinal fluids were uniformly reported as normal. The majority of these patients recovered in thirty to sixty days without any residual symptoms. As the study of these cases did not include roentgenograms of the chest it is possible that some, at least, were examples of primary atypical pneumonia.

A review of the literature has failed to reveal a report of myelitis occurring as a complication in a proved case of primary atypical pneumonia.

The complete recovery of the patients described in the 1917-1925 reports paralleled the situation in our own case and was in decided contrast to the types of myelitis produced by known bacterial infections, which usually result in prolonged illness and often leave the patient with permanent motor and sensory disabilities.

The case here described differs from those previously reported in the following features: (a) It occurred in a proved primary, atypical pneumonia, (b) there was no sensory involvement which could be objectively demonstrated, (c) the spinal fluid was distinctly abnormal. The symptomatology, spinal fluid findings and clinical course of the disease were closely comparable to those of other conditions known to be produced by virus invasion of the central nervous system. If this assumption is correct, it tends in a limited way to support current views with regard to the etiology of primary atypical pneumonia.

SUMMARY

- 1 A severe but transient meningomyelitis occurred as a complication of primary atypical pneumonia.
- 2 The character of the primary disease was established by physical and roentgen examinations and by the clinical course.
- 3 The principal neurologic manifestations were interference with the muscles of respiration, bladder atony, loss of sphincter control and paralysis of the lower extremities, all developing on the twelfth day of the disease.
- 4 The patient subsequently recovered without evidence of residual neurologic disability.

Council on Industrial Health

THE COUNCIL ON INDUSTRIAL HEALTH HAS PREPARED THE FOLLOWING REPORT AS AN AID TO PHYSICIANS IN INDUSTRY AND TO COMMITTEES ON INDUSTRIAL HEALTH IN STATE AND COUNTY MEDICAL SOCIETIES CALLED ON TO FORMULATE STANDING ORDERS FOR INDUSTRIAL NURSES

C. M. PETERSON, M.D., Secretary

STANDING ORDERS FOR NURSES IN INDUSTRY

For some time the medical and nursing professions have been concerned about the employment of nurses in industry without adequate medical supervision. The Council on Industrial Health has therefore been requested to formulate standing orders for industrial nurses which can be adapted to meet the requirements of individual industrial medical departments. If no responsible industrial medical authority exists it is recommended that the nurse request helpful instruction in this regard from the committee on industrial health of the appropriate county or state medical society.

GENERAL RELATIONSHIPS

Standing orders represent a preliminary understanding between physician and assisting personnel about routine conduct of a medical service. In establishing such orders in an industrial medical department, several considerations need to be borne in mind.

- 1 The greater the amount of personal supervision exercised by the physician directly in the industrial environment the better is the industrial health service.
- 2 Standing orders cannot be written to meet every situation likely to arise in industry. They must be modified to meet specific requirements and in accordance with the training and professional competence of the assisting personnel. They should be signed by the supervising medical authority and posted prominently in the medical department.
- 3 The nurse in industry should assume no responsibility for service outside the field of her professional training. This applies particularly to individual case management, from which the nurse should rigidly abstain except:
 - (a) In emergencies demanding immediate independent judgment and action.
 - (b) Procedures of preliminary or first aid nature routinely required by reason of the nature of the work and which are clearly stipulated in the standing orders.

This statement confines itself mainly to these last named aspects of mediconursing relations in industry. Additional reports on other functions of industrial nurses will follow as needed.

EMERGENCY PROCEDURE IN INDUSTRY

General principles which operate in all emergency situations apply to industry as well. They are:

- 1 Call a physician immediately.
- 2 Stop bleeding.
- 3 Restore breathing.
- 4 Prevent shock and infection.
- 5 Do no more than is actually needed.

The supervising physician should assure himself that these instructions are thoroughly understood and should institute special training when necessary. Nurses in industry should qualify as first aid instructors.

Emergency Supplies—Emergency packs with essential sterile supplies should be available at all times in the medical department and in first aid kits suitably located throughout the plant. Regular inspection is necessary.

Hemorrhage—Bleeding calls for immediate attention. The nurse should notify the physician and, until he arrives, proceed as follows:

- 1 Expose the wound.
- 2 Remove obvious foreign matter.
- 3 Apply pressure.

Direct manual or bandage pressure firmly applied over sterile gauze packing at the bleeding site will effectively control mod-

erate hemorrhage. Indirect compression is indicated in excessive bleeding not controllable by direct methods. Digital compression over the vessel against underlying structures either adjacent to the wound or at the nearest pressure point will usually suffice until the physician arrives. Indirect pressure should be applied proximal or distal to the wound, in keeping with the arterial or venous character of the bleeding. Hemostats or clamps should be applied whenever the emergency warrants it.

Avoid applying a tourniquet if possible. If severe bleeding in an extremity suggests the use of a tourniquet, apply a blood pressure cuff.

The nurse should remember that:

- 1 A direct pressure bandage should not act as a tourniquet.
- 2 A tourniquet must be periodically released at least every fifteen minutes.
- 3 No dressing should be applied over a tourniquet.
- 4 Asepsis must be observed at all times.

Asphyria—Cessation of breathing from any cause demands:

- 1 Artificial respiration *at once* and *at the site of the accident*.
- 2 Notification of the physician.
- 3 Maintenance of body warmth. Avoid excessive heating.

All industrial nurses should demonstrate ability to apply artificial respiration by the prone pressure method and should realize the need for its continuous application until breathing is restored or until careful repeated medical examination advises otherwise.

Shock—*Early and adequate shock treatment is life saving. Do not delay.*

Common symptoms of shock following injury are pallor, perspiration and rapid thready pulse. Emergency management by the nurse should include:

- 1 Notification of the physician.
- 2 Removal of cause. If shock is due to hemorrhage, control it. If it is due to trauma not associated with bleeding, all active treatment of injury should be deferred until shock management has been instituted. Wounds should be covered with sterile dressings to prevent infection.
- 3 Relief of pain. $\frac{1}{2}$ to $\frac{1}{4}$ grain (0.010 to 0.016 Gm.) of morphine sulfate, repeated if necessary or barbiturates as routinely ordered except in injuries to the head or trunk.
- 4 Keeping the patient warm, dry, and on his back with his head low. Avoid overheating.

ROUTINE NURSING CARE OF INJURIES

Successful medical management of industrial injuries depends on:

- 1 Prompt treatment.
- 2 Meticulous cleansing and dressing.
- 3 Examination of deep as well as of superficial structures.

To accomplish these aims the routine functions of the nurse should be confined to care of minor wounds as follows:

- 1 Protect wound with sterile gauze while adjacent area is cleansed with soap and water or solvent.
- 2 Discard protective dressing and clean wound margins.
- 3 Irrigate wound with sterile water or isotonic solution of sodium chloride.
- 4 Apply antiseptic or physician's choice.
- 5 Apply dry sterile dressing interlining as little as possible with tunction. Sterile dressings should be covered with protective material for use at work. The worker should be instructed not to remove the dressing but to return to the medical department if it becomes loosened or uncomfortable.

The nurse should do no more than is actually needed. The following conditions require direct medical supervision:

- 1 Wounds requiring debridement.
- 2 Those with obvious or suspected involvement of deep structures.
- 3 Wounds with edges which do not approximate.
- 4 Wounds about the head and face.
- 5 Contaminated wounds requiring tetanus prophylaxis.

Management of Common Injuries—Injuries most likely to be encountered in industry include the following conditions

- 1 Abrasions Clean and apply dry dressing Extensive or deep loss of skin, especially about the fingers and hands, needs medical attention
 - 2 Contusions Treat with cold compresses directly following injury, later with moist heat If soreness or disability persists or if deep involvement is suspected, refer to the physician
 - 3 Lacerations Clean and apply dressing as directed Any possibility of injury to joints, nerves or tendons should be brought to the physician's attention at once
 - 4 Puncture Wounds Puncture wounds through the skin need direct medical supervision to avoid or treat severe infection If superficial, clean and apply sterile dressing
 - 5 Slivers and Splinters Penetration through the skin by slivers or splinters always carries the risk of an infected puncture wound and should be treated as such Those lodged superficially and easily removed without added trauma or incision may be extracted aseptically by the nurse
 - 6 Burns and Scalds Clean minor burns with soap and water Apply petrolatum or 5 per cent boric acid ointment, bandaging firmly without interfering with function Leave blisters alone
In all other cases
 - (a) Notify the physician
 - (b) Cover the burned area with a sterile dressing or sheet moistened with isotonic solution of sodium chloride or 5 per cent sodium bicarbonate solution
 - (c) Combat pain and shock
- In the absence of specific orders, chemical burns should be treated by irrigation or immersion in water for at least twenty minutes and then by dressing
- 7 Sprains and Strains Treat first with cold compresses, elevation of the part and rest A physician's advice is necessary regarding strapping, other methods of support or fixation, further examination or special therapy

FRACTURES

Preliminary steps for the nurse are

- 1 Call a physician at once
- 2 Keep the patient quiet and warm
- 3 Immobilize before any movement is attempted
- 4 Do not attempt reduction
- 5 If the fracture is compounded, cover the site of the fracture with a dry sterile dressing *Do not cleanse or reduce*

Special instruction in splinting should be provided every industrial nurse

EYE INJURIES

Rigid aseptic technic must be scrupulously observed in all eye conditions Never attend consecutive patients without sterilization of instruments and careful hand washing Remember that early symptoms of infection simulate foreign body

Minor Burns—Do not apply ointments to minor burns of the skin about the eye Apply a sterile dressing and refer to the physician

Burns of the Eye—1 Chemical Burns Irrigate chemical burns of the eye *copiously* and *at once* with water, preferably by immersion Neutralizing solutions are usually inadequate or unavailable The rapidity with which the irrigation occurs is more important than the type of solution used Continue to irrigate at least twenty minutes by the clock

2 Hot Metal Burns Apply a sterile pad and refer at once to the physician Do not irrigate An anesthetic should be applied as ordered by the doctor

Every burn of the eye should receive competent medical attention early

Foreign Bodies—The nurse should attempt to remove only those foreign bodies of the eye which can be readily located and which can be easily washed out or removed with a dry

sterile cotton applicator An antiseptic may be applied if the physician so orders

Direct medical care is essential

- 1 If the foreign body cannot readily be located Stains to aid in the location of foreign bodies should be used only on specific medical order

- 2 If removal requires any instrumentation

- 3 If irritation or pain persists after removal

No person with an eye injury should be discharged without examination by a physician

"Flash" Injury—First aid treatment should include

- 1 Local anesthetic as ordered

- 2 Cold compresses

- 3 Sedatives

Persistent pain following flash needs medical examination and treatment

Conjunctivitis—Conjunctivitis or other forms of conjunctival irritation should be referred routinely to the physician or ophthalmologist

HEAD INJURIES

Until the physician takes over, the nurse should

- 1 Keep the patient lying down

- 2 Elevate the head

- 3 Apply ice cap or cold compress *No sedatives*

- 4 Record pulse and respiration every ten minutes

Clip or shave and cleanse areas adjacent to scalp lacerations, and cover with a sterile pad

CHEST AND ABDOMINAL INJURIES

Contusions of the chest and abdomen with or without external evidence of injury may result in trauma to underlying organs Until seen by the physician, such patients must be

- 1 Kept warm and quiet

- 2 Allowed no sedatives

- 3 Have pulse, temperature and respiration recorded frequently

- 4 Suitably bandaged to avoid contamination

In case of abdominal injury give nothing by mouth

NONOCCUPATIONAL ILLNESS

Treatment of injury or illness which has no relation to occupation is not a function of the industrial medical department except

- 1 First aid for emergency sickness Such measures as the situation demands must be taken until notification of the family physician discharges responsibility

- 2 For minor ailments which temporarily interfere with an employee's comfort or ability to complete a shift and for the relief of which a physician would not ordinarily be consulted

In all relationships of this kind, judgment and tact are required of the industrial nurse Several principles apply

- 1 Before giving any treatment, the temperature, pulse, general appearance and a history of the presenting complaint should be recorded

- 2 Palliative treatment, especially for chronic or recurring disorders, should not be repeated

Every properly trained nurse understands the difference between attention of this kind and systematic treatment

CARE OF MINOR ILLNESS AND SYMPTOMS

Persistent or augmenting symptoms of irritation, discomfort or disability suggest faulty work environment The nurse should not hesitate to ask for medical examination of workers and of the premises

Fever—A rise in temperature of 1 degree suggests medical consultation before work is resumed Findings should be checked by repeated thermometer recordings

Headache—Record temperature If headache is accompanied by dizziness, nausea, vomiting, stiff neck, injury, history of recurrence, fever, general malaise or other symptoms the patient

needs medical attention. It not give an analgesic as ordered by the physician.

Remember that headache or dizziness may be precursory signs of intoxication.

Unconsciousness—1 Fainting. Usual symptoms are pallor, with shallow breathing, slow and weak pulse. Period of unconsciousness is of short duration.

Keep the patient lying down with head lowered until fully recovered. Be sure the patient has plenty of fresh air. Clothing should be loosened and stimulating inhalants used such as ammonia or smelling salts.

2 Other causes. If other signs are present or if unconsciousness persists longer than a few minutes, call for medical assistance. *Give nothing by mouth.*

Toothache—If there is a cavity, the nurse may pack it with cotton dipped in oil of cloves for temporary relief. For further examination and treatment refer to a dentist.

Nosebleed—Spontaneous nosebleed may be treated by cold packs or pinching the sides of the nose against the septum. Keep the patient sitting erect or standing and loosen the collar if it tends to constrict the neck. Advise the patient not to breathe or blow through the nose for an hour or two after bleeding has stopped.

Bear in mind that certain occupational exposures are manifested by nasal damage and bleeding.

Sore Throat—Patients with sore throat may be given a hot saline gargle if they have a normal temperature. Do not "paint" the throat. Any persistent sore throat or one associated with fever needs medical care at home.

Respiratory Irritation or Infection—Repeated or persistent signs of bronchial or chest irritation without associated infection suggests an unfavorable occupational exposure. A plant hygiene survey is indicated.

Persons having acute respiratory infections with elevated temperature, cough, sneezing or nasal discharge should be sent home for proper segregation, rest and medical attention. In mild infections work may be continued if under medical or nursing supervision simple measures will control symptoms and prevent spread.

Available medical evidence at the present time cannot support routine administration of cold vaccines or vitamin preparations as methods of reducing the incidence or severity of acute respiratory infections.

Frequent colds or chronic respiratory conditions require special medical consideration.

Abdominal Distress—Early signs of occupational intoxication may be abdominal in character. In any case abdominal distress, nausea or pain, especially if severe or persistent, requires competent medical diagnosis and management.

Laxatives should never be dispensed from an industrial medical department.

Dysmenorrhea—Painful menstruation not associated with fever or gastrointestinal disturbances may be treated with an analgesic ordered by the physician and the patient placed at rest with heat to the lower part of the abdomen. If there is no relief or if other signs or symptoms present themselves she should be referred to her physician.

Patients with recurrent severe dysmenorrhea should not be given palliative treatment. They should be referred for examination and treatment.

DERMATITIS

Management of skin disorders in industry depends on cause.

Specific Irritants—Materials or processes in the plant capable of causing skin disease should be identified and special orders provided for control. Competent dermatologic consultation is essential in all obscure or refractory situations.

Nonspecific Skin Disease—Nonspecific skin irritation in industry is almost entirely assignable to faulty personal hygiene. The nurse can do much to improve washing routine, the use of dependable protective coverings, the wearing of clean work clothing, maintenance of satisfactory housekeeping in the plant and the general maintenance of accepted hygienic procedure.

PREGNANCY

A definite policy regarding employment during pregnancy should embrace the following recommendations:

- 1 The employee should notify the proper authority in industry about her pregnancy within the first trimester.
- 2 She should obtain a statement from her own physician—
 - (a) That her work is not contraindicated.
 - (b) Regarding the length of time she should work.
- 3 Special attention should be given to the nature of the work. Pulling, pushing and lifting must be kept within safe limits. Rest periods will tend to minimize emotional and physical instability during pregnancy.
- 4 Ordinarily work should terminate by the thirty-second week (within six weeks of term). If contraindications arise within this period, the employment should stop.
- 5 Return to work is inadvisable before six weeks after delivery and then only on notification of the employer by the physician.

EQUIPMENT AND SUPPLIES

Space which can command privacy and which can be kept clean and properly prepared for emergency and routine services by the nurse should be provided in the plant. Special attention should be given to heating, light, ventilation and accessibility.

Furnishings and Supplies

General Furnishings

- | | |
|--------------------------|------------------------|
| 1 Sink | 9 Foot pedal waste can |
| 2 Instrument cabinet | 10 Waste basket |
| 3 Sterilizer | 11 Storage cabinets |
| 4 Dressing table | 12 Paper towel rack |
| 5 Leg rest | 13 Adhesive rack |
| 6 Cot | 14 Record file |
| 7 Stretcher | 15 Scale |
| 8 Mirror 10 by 12 inches | |

Instruments and Supplies

- | | |
|-------------------------------|-----------------------------|
| 1 Scalpels | 13 Adhesive plaster |
| 2 Splinter forceps | 14 Cotton |
| 3 Tissue forceps | 15 Applicators |
| 4 Hemostatic forceps | 16 Assorted sutures |
| 5 Bandage scissors | 17 Assorted splints |
| 6 Surgical scissors | 18 Assorted jars and basins |
| 7 Hand magnifying glass | 19 Test tubes |
| 8 Syringes | 20 Safety razor and blades |
| 9 Assorted hypodermic needles | 21 Hot water bottle |
| 10 Assorted surgeons' needles | 22 Ice cap |
| 11 Needle holder | 23 Crutches |
| 12 Assorted bandages | 24 Tourniquet |

Drugs (as ordered by the physician or medical adviser)

- | | |
|---------------|----------------------------|
| 1 A stimulant | 3 Analgesics and sedatives |
| 2 An emetic | 4 Antiseptics |

The accompanying check list of furnishings and supplies suitable for a small plant dispensary should be augmented by equipment for emergency treatment or other special medical requirements as ordered by the plant physician or other medical adviser.

INSECT VECTORS OF POLIOMYELITIS

In 1911 Flexner and Clark¹ allowed flies to feed on the spinal cords of monkeys which had died of experimental poliomyelitis. Insects thus contaminated harbored infectious doses of the virus for at least forty-eight hours. This observation was followed by a long series of experiments by other investigators² in which unsuccessful attempts were made to transmit poliomyelitis to rhesus monkeys by houseflies, biting flies, body lice, head lice, bedbugs, fleas and mosquitoes. In face of these repeated failures, supplemented by the growing belief that poliomyelitis is a "respiratory disease," entering the body only through the olfactory nerves, many clinicians believed that it was "unnecessary" to try to bring insects into the epidemiologic picture.

Twenty years later, however, following a shift of clinical interest to the possibility that human feces and sewage might be the main sources of infection, insect vectors again became of logical interest. Rosenow³ reported that flies collected during the 1935 Kentucky epidemic harbored infectious doses of poliomyelitis virus, typical paralysis developing in 1 out of his 3 rhesus monkeys inoculated intracerebrally with fly filtrates. These results were challenged by other investigators,⁴ who reported only negative results with houseflies, mosquitoes and other insects collected during other epidemics.

Methods of detecting poliomyelitis virus in stools and sewage have been greatly improved since that time, the most important improvement being the substitution of highly susceptible Java monkeys (*Cynomolgus*) for

the more resistant rhesus and green African monkeys previously used. Adopting these newer methods, three groups of investigators⁴ reported positive results with fieldflies collected in epidemic areas. A detailed account of the results obtained by one of these groups is currently reported by the late Dr. James D. Trask and his colleagues⁵ of the Department of Pediatrics of Yale University.

During the 1941 epidemic of poliomyelitis the Yale investigators caught numerous samples of nonbiting fieldflies in traps set within the yard near the privy or near a house in which 1 or more cases of poliomyelitis had occurred. Samples of biting insects were also collected from the backs or sides of cows tethered in the epidemic areas. The flies were usually transferred to glass jars and stored at refrigeration temperature for a period of three to seven days before using. Two types of inoculums were prepared from these insects. In the first type 100 to 600 dead flies together with the inside contaminated surface of the glass container were washed with 50 cc of distilled water. The washings were centrifuged at low speed and the midlayer set aside for nasal instillations. Fifteen per cent ether was added to the remaining parts of the washings for bactericidal purposes. The etherized sample was used for intra-abdominal injections. In their second type of inoculums from 100 to 500 flies were emulsified in 200 cc of distilled water. The resulting emulsions were centrifuged and prepared in the same way for inoculation tests.

Thirty-nine washings or emulsions representing 19 different fly samples were each inoculated into 1 monkey. In most cases the inoculation was made by two routes: 2 cc given intranasally on each of three successive days, and 10 to 20 cc of the etherized preparation given intra-abdominally as one dose. Animals subsequently showing signs of poliomyelitis were killed and studied microscopically, and attempts were made to pass the virus to a second generation by means of multiple intracerebral inoculations. Briefly summarized, poliomyelitis virus was definitely isolated and identified from 4 of the 19 different fly samples, with "equivocal" results from a fifth sample. Positive results were obtained with doses representing as few as 14 flies (average 70 flies). All positive results were obtained with *Cynomolgus* monkeys, all tests with rhesus and green African monkeys being negative. No positive takes were obtained with the mosquitoes and biting flies similarly tested.

The nonbiting fly species showing positive results did not differ from those giving negative reactions. The dominant species in each group were green bottleflies and blowflies, the common housefly being present in small numbers in only 2 of the 4 positive specimens.

3 Rosenow, E. C., Smith, L. H., and McCormack, A. T. *Kentucky M J* 35: 437 (Sept) 1937.

4 Tacony, J. A., Takacs, W. S., and Tischer, Linda A. *Proc Soc Exper Biol & Med* 48: 637 (Dec) 1941. Paul, J. R., Trask, J. D., Bishop, M. B., Melnick, J. L., and Casey, A. E. *Science* 94: 395 (Oct 24) 1941. Sabin, A. B., and Ward, Robert. *Science* 94: 590 (Dec 19) 1941.

5 Trask, J. D., Paul, J. R., and Melnick, J. L. *J Exper Med* 77: 531, 545 (June) 1943. Dr. Trask died on May 24, 1942.

Practically the same results had been previously reported by Sabin and Ward⁶ who were able to isolate poliovirus from 8 of 15 samples of houseflies collected during 1941 outbreaks of the disease. Their positive results also were obtained with cynomolgus monkeys. Their fly pools also usually consisted mainly of green bottleflies and black blowflies. Loomer, however, reported one successful take with a rhesus monkey inoculated intracerebrally with an emulsion of houseflies trapped near an open sewer during the same epidemic.

Trask's positive results were all from fly samples collected near a potential (though not proved) source of virus in the form of exposed human feces of recent origin. The Yale investigators, however, warn against reading an epidemiologic implication into their results, since the presence of virus in their positive samples might be merely a resultant and not a "causal factor" in the local epidemic. Whether or not the virus can multiply on or within the contaminated flies has not yet been determined.

OBSTETRIC AND PEDIATRIC CARE OF WIVES AND INFANTS OF ENLISTED MEN

California and Western Medicine for August 1943 takes to task the action of the federal Children's Bureau in providing payment for the obstetric care of the wives of enlisted men and for the care of their children. objection is not made to the payment or to the care but to the technique and rate of payment. Incidentally, the editorial in *California and Western Medicine* asks why the "national mouthpiece of organized medicine" has made no editorial comment and calls attention to what are said to be the only two items on the subject which appeared in *THE JOURNAL*. Elsewhere in this issue (Organization Section, page 1257) appears some of the correspondence on the subject between Dr. George H. Kress, Secretary-Editor of the California Medical Association, and Dr. Olm West, Secretary of the American Medical Association.¹

The readers of *California and Western Medicine* should have the accurate information here published.

The article by Dr. Edwin F. Daily in *THE JOURNAL* for July 31, 1943 indicates that the program which received its first special appropriation in March 1943 was already operating by July 31 in thirty-seven states, Hawaii, Alaska and the District of Columbia and that the health agencies of several of the remaining eleven states were at the time completing their plans for

administering the program. More than 95 per cent of payments were for maternity care and less than 5 per cent for pediatric care. It will be observed that under this program plans are developed and administered by state health agencies and then approved by the chief of the Children's Bureau.²

At the meeting of the House of Delegates held this year in Chicago several resolutions were introduced relating to this activity of the Children's Bureau. The House of Delegates was confronted with a proposal from the state of New York to the effect that the federal security law be changed in such manner as to assure payment of the physician and with another resolution presented by Dr. John H. Fitzgibbon of Oregon to the effect that approval be expressed of federal assistance to the wives and children of servicemen provided that any funds allocated for professional services be given to the wives of enlisted men, such patients then to secure the services of physicians as they themselves deemed proper and the fees for professional services to be decided by mutual agreement between the patients and the attending physicians. The reference committee of the House of Delegates brought in a report that the action of the federal government in making funds available for maternity and infant care for the wives of enlisted men be approved and that adoption be urged of a plan under which the federal government will provide for the wives of enlisted men a stated allotment for medical, hospital, maternity and infant care similar to the allotments already provided for the maintenance of dependents, leaving the actual arrangements with respect to fees to be fixed by mutual agreement with the wife and the physician or her choice. The reference committee at the same time disapproved the resolution from the state of New York because it involves the introduction of a third party—a party coming between the patient and the physician.

In his editorial Dr. Kress asks "Is it fair to a small group of constituent state medical associations to make them carry on this battle against governmental intrusion into the domain of private medical practice? On a subject of national scope, is it not to be expected that the national organization will point the way?" Certainly the detailed statement of Dr. Olm West sent to Dr. Kress, which Dr. Kress says will be placed in the files indicates how definitely the national association has pointed the way, indicates how certainly the House of Delegates has acted in the matter, indicates finally that the editor of *California and Western Medicine* went to press with his periodical before he received sufficient factual information to warrant the statements that are made.

2. California was allocated \$20,000 during the first and second quarters of 1943 under the federal Social Security Act to be used for maternal and child health. Sufficient maternal and child health funds were still available in the state for such services during the third quarter of 1943. Fifty thousand dollars was being requested by California for the fourth quarter of 1943.

⁶ Sabin, A. B. and Ward, Robert. *Science* 95: 300 (March 20) 1942.

¹ Dr. Kress wrote to Dr. West on August 6 that letter was received in the office of Dr. West on August 9 at 8:23 in the morning and was answered by a letter sent on the afternoon of August 10. The communication written by Dr. Kress on August 17, received in the headquarters office on August 20 at 10:37 a.m. states: "Dr. West's reply was received too late to be of use in my August editorials for *California and Western Medicine*. I am very glad to have this information for our files [sic]."

Never before in the history of our country or of the world has there been such unrest as is now apparent among medical men and among some of the constituent state organizations of the American Medical Association. The unrest appears to be stimulated by fears related to proposed national legislation—such as the Wagner-Murray-Dingell bill, S. 1161—and efforts on the part of various agencies of the government to take over medical practice. Such efforts are not new, they have been persistent since 1928. During the fifteen years that have elapsed the maximum accomplishment in the way of legislation injurious to the quality of medical practice for the American people has been permissive legislation for some agencies of the government to utilize the services of osteopaths and some activities on the part of various government bureaus utilizing their own regulations, which have gone beyond the powers granted to them by the acts under which they operate.

The wives of enlisted men who need obstetric service should certainly be able to obtain good obstetric service and, when funds are not available, to receive aid for that purpose. This applies equally to the pediatric care necessary for the children of enlisted men. The service that these men render to the nation in offering their lives in its defense merits the most that the nation can give them. In many instances, no doubt, enlisted men are the possessors of considerable funds accumulated previously to their enlistment. In many instances, no doubt, these men married during the period of enlistment and their wives are still residents in the home of parents well able to care for their every need. In a proposed army of more than ten million men, however, those financially competent to this extent would probably constitute a minority. Moreover, those who are financially competent are not in the vast majority of cases availing themselves of the fees established by or the money provided by the federal Children's Bureau. They are now choosing, as they have in the past, the obstetrician and hospital of their choice, and they are paying the sums requested by such obstetricians for their services. Even this, however, should not weigh against the fundamental principle reiterated by the House of Delegates in the action taken at the meeting in June 1943. It was the belief of the House of Delegates that the funds available should be paid to the patient and that the matter of payment to be rendered was a matter for determination between the patient and the physician.

Notwithstanding these principles, many physicians and many state departments of health have accepted the proposals of the Children's Bureau and are giving obstetric and pediatric services in accordance with the plans that have been described. The medical societies of Michigan, Oregon, Ohio and California have recorded themselves as opposed to such plans.³ The opposition,

as stated by the Michigan State Medical Society, is based on the belief that this will encourage the development of a poor quality of obstetric and pediatric care, establish a precedent for further extension of governmental interest into the private practice of medicine, commit to such governmental activities those members of the medical profession who are in the military service and who have not had opportunity to express their opinions, and open the door to governmental medical service for all, without economic distinction or determination of need and establish a fee schedule. The real test of opposition to the program is the extent to which the individual physician will refuse to participate in its operation and the extent to which state medical organizations will express officially their unwillingness to approve. In this connection Dr. Daily concludes his article with this statement: "The cooperation of practicing physicians and hospital administrators, on whom much of the burden of the program ultimately rests, has made it possible for most of the state health agencies to establish these statewide services for the wives and infants of enlisted men in the armed forces."

Current Comment

ANTIBACTERIAL SUBSTANCES FROM ASPERGILLUS MOLDS

The remarkable effects of penicillin in certain bacterial infections have aroused interest in the production of antibacterial substances by fungi other than *Penicillium notatum*. Wiesner¹ found that strains of *Aspergillus clavatus* produced a substance which had bacterial as well as bacteriostatic effects on organisms not attacked by penicillin. Waksman and his associates² report the results of studies of antibiotic or antibacterial substances obtained from cultures of *Aspergillus fumigatus* and *Aspergillus clavatus*, isolated from soils, stable manure and composts. Grown in a glucose-nitrate medium *A. fumigatus* produces an extractable, crystallizable, antibacterial substance called fumigacin, which is active against gram positive bacteria but has only little effect on gram negative organisms or fungi. *Aspergillus clavatus* also produces an antibacterial substance on synthetic mediums. This substance is called clavacin. It differs from fumigacin both chemically and in its antibiotic actions, being almost as active against gram negative as against gram positive bacteria. It has not as yet been isolated in crystalline form. Only six of fifteen strains of *A. clavatus* produced clavacin in considerable amounts. Waksman and Schatz² caution against too hasty generalizations of the power of certain fungi to produce antibacterial substances based on the results of the study of single strains of a given fungus. Fumigacin and clavacin are notable

Two Antagonistic Fungi, *Aspergillus Fumigatus* and *Aspergillus Clavatus*, and Their Antibiotic Substances J Bact 45 233 (March) 1943

³ A statesmanlike letter by the president of the Ohio State Medical Association, Dr. C. C. Sherburne, indicates that the whole subject was thrown into the political arena in Ohio, and this made the position of the medical profession most difficult.

additions to the antibiotic agents derived from fungi. They differ in many respects from penicillin. Both are fairly toxic to animals.¹ Whether their selectively bacteriostatic and bactericidal properties can be used to advantage in treatment remains to be determined.

MERCURIALS AS "PRESERVATIVES"

In a recent study of protein sulphydryl groups Hellerman, Chinard and Deitz¹ point out that organometallic compounds of the type R-Hg-X, such as phenylmercuric hydroxide and its derivatives form poorly dissociated protein mercaptides by combination of the organic mercurial with protein thiol groups. According to Fildes² the formation of such mercaptides is the basis for the bacteriostatic action of mercury. Such sulphydryl groups are present however not only in bacteria but in plasma and other proteins. Bacteriostatic action of such organomercuric compounds in the presence of serum is therefore largely prevented by competition of reactive groups on the serum proteins for the mercury. This presumably is the basis of the finding³ that the 'activity of a mercurial antiseptic in serum is reduced to 0.33-0.007 per cent of its activity in saline.' Ignoring of these simple chemical facts can be responsible for very serious occurrences, such as the arrival in England of plasma "preserved" with 1:10,000 merthiolate containing viable micro-organisms. Johnson and Melenev⁴ conclude

In our experience 1:10,000 merthiolate has not been able to insure the sterility of stored liquid plasma. The contaminations reported in this paper in plasma-saline mixture containing 1:10,000 merthiolate are sufficient to be an argument against its use. The material found to be contaminated when tested after its arrival in England is further evidence that 1:10,000 merthiolate cannot be considered the ideal preservative for plasma. Further research work in this field is indicated.

POLIOMYELITIC DEGENERATION OF MOTOR END PLATES

Cellular and vascular reactions in the central nervous system during the acute stages of poliomyelitis have been exhaustively studied. Report has not thus far been made, however, of the preceding or accompanying morphologic changes in the peripheral motor nerve endings and muscle fibers. To supply this deficiency, Carev¹ of the Department of Anatomy, Marquette University School of Medicine, has studied the microscopic changes in these peripheral structures. The results promise to be of clinical interest. Eight to twenty days after rhesus monkeys were inoculated intracerebrally with the Lansing strain of poliomyelitis virus (first to

fourth day of paralysis) the animals were chlorotormed, parts of each paralyzed muscle were fixed and stained with a modified gold method.² Carefully teased pieces of the impregnated muscles were photographed under low magnification corresponding muscles from normal monkeys being used as controls. The photographs showed a 20 per cent reduction in the number of motor end plates by the first day of recognized paralysis, with residual end plates often retracted into ball-like masses or swollen and granular. By the second to fourth day approximately 50 per cent of the end plates had disappeared with retraction of the completely denuded axis cylinders. The rates of degeneration were not equal in different parts of the same muscle, certain areas showing a total absence of motor end plates. During the early paralytic stages, masses of auripilous inclusion bodies were present at the site of the original myoneural junction of many muscles. These ephemeral inclusion masses usually disappear by the seventh day of paralysis. The end plate studies are being continued on a larger series of experimental animals.

HYPOTRYPTOPHANIC STERILITY

Failure of farm animals to reproduce when placed on low protein diets¹ is of major economic interest. Study of the physiology of this nutritional sterility was facilitated when it was found that female rats placed on a low protein diet also would not reproduce.² Albanese and his colleagues³ of Johns Hopkins University attribute this reproductive failure to an inadequate intake of certain amino acids. Normal adult male and female rats, for example, were reared on a stock diet and then mated. As soon as vaginal smears showed the presence of sperm, half of the females were segregated in individual cages and fed a tryptophan deficient diet *ad libitum*, an equal number of inseminated females being maintained as controls on the stock diet. After a gestation period of twenty-two to twenty-four days each normally fed control female gave birth to a litter of from 4 to 10 young (average 7 young). None of the inseminated females placed on the deficiency diet gave birth to young, the deficiency group showing a 100 per cent reproductive failure. A second group of inseminated females were killed on the ninth, eleventh, thirteenth and fourteenth days after being placed on the deficiency diet. Embryos of normal size and appearance were present on the ninth day, but by the fourteenth day almost complete resorption had taken place. From these experiments it would seem that tryptophan is an essential dietary factor for normal gestation in rats and that the available reserves of this amino acid in maternal tissues is depleted within ten days on a tryptophan deficient diet. Whether or not reproductive failure of domestic animals on low protein diet is due solely to tryptophan deficiency, however has not yet been determined.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

ARMY

COLONEL JENSEN APPOINTED DEPUTY AIR SURGEON

Col Walter S Jensen of the Medical Corps has been appointed Deputy Air Surgeon of the Army Air Forces. Brig Gen David N W Grant, Air Surgeon, has announced Colonel Jensen vacated the position of executive officer and was succeeded by Col Henry C Chenault, formerly chief, Professional Division, Air Surgeon's Office. Colonel Chenault's vacancy was taken by Lieut Col George L Ball.

THE ETOUSA SOCIETY OF OPHTHALMOLOGY

The Etousa Society of Ophthalmology was conceived by United States Army ophthalmologists on the occasion of the British Congress of Ophthalmology. Under the direction of Lieut Col Derrick T Vail, a preliminary meeting was held in the London Senior Officer's Mess on May 1 at which Brigadier Sir Stewart Duke-Elder was guest of honor. Plans were made for bimonthly meetings to be held at a different general hospital and it was decided to publish a bimonthly journal.

The first scientific meeting of the society was held at the Second General Hospital near Oxford, England, on July 10, attended by thirty American and two Canadian army officers, Lieut Comdr Edwin Dunphy of the Navy and one civilian, all ophthalmologists. The program arranged by Capt F P Calhoun included five papers in the morning, the climax of which was "War Gas Injuries of the Eyes" by Lieutenant Commander Dunphy. In the afternoon there were exhibits of photographs, drawings and movies with the presentation of 8 cases. The meeting ended with a dinner-dance given by the nurses. The next meeting will be held at the Fifth General Hospital in September.

PHARMACY CORPS ESTABLISHED IN MEDICAL DEPARTMENT

The Seventy-Eighth Congress passed Public Law No 130 establishing a Pharmacy Corps in the Medical Department of the Army to consist of seventy-two officers in grades from colonel to second lieutenant. Appointments in the Pharmacy Corps will be made in the grades of second lieutenant from pharmacists between 21 and 32 years of age who are graduates of recognized pharmacy schools requiring four years of instruction, under such regulations as the Secretary of War shall prescribe. Officers of the Pharmacy Corps will be promoted to first lieutenant after three years' service, to captain after six years' service, to major after twelve years' service, to lieutenant colonel after twenty years' service and to colonel after twenty-six years' service, provided officers in the Regular Army holding commissions in the Medical Administrative Corps on the date this law was enacted shall be transferred to the Pharmacy Corps and commissioned in grade in that corps in addition to the seventy-two officers authorized for the Pharmacy Corps. The act was approved on July 12.

AVIATION PHYSIOLOGISTS

A routine course of instruction for aviation physiologists began on August 2 at the School of Aviation Medicine, Randolph Field, Texas. Among the students enrolled are First Lieuts Aaron Grossman, Morton McMichael, Emanuel Marcus and Frederick S Spiegel.

MORE PHYSICAL THERAPY AIDES WANTED

Physical therapy aides are now serving in 140 army hospitals in the United States and in 32 overseas. The administration of physical therapy requires knowledge of anatomy, physiology and pathology. It includes treatment by means of massage, exercise, electricity, water and various forms of heat. The Medical Department has expanded its training program so that student physical therapy aides are being trained at Walter Reed General Hospital, Washington, D C, Fitzsimons General Hospital, Denver, Brooke General Hospital, Fort Sam Houston, Texas, Army and Navy General Hospital, Hot Springs, Ark, and O'Reilly General Hospital, Springfield, Mo. Over twenty civilian institutions are also cooperating in training physical therapy aides. Many of these courses have been intensified and reduced to courses of six months' duration to meet the emergency. Civilian hospitals conducting such courses are Children's Hospital, Los Angeles, College of Medical Evangelists, Los Angeles, University of California Hospital, San Francisco, Stanford University, Palo Alto, Calif, Northwestern University Medical School, Chicago, State University of Iowa Medical School, Iowa City, Bouve-Boston School of Physical Education, Boston, Harvard Medical School, Cambridge, Mass, Boston University-Sargent College of Physical Education, Boston, University of Minnesota, Minneapolis, Mayo Clinic, Rochester, Minn, Barnes Hospital, St Louis, St Louis University School of Nursing, St Louis, University of Buffalo School of Nursing, Buffalo, Hospital for Special Surgery, New York, New York University, New York, Cleveland Clinic Foundation Hospital, Cleveland, D T Watson School of Physio-Therapy, Leetsdale, Pa, Graduate Hospital of the University of Pennsylvania, Philadelphia, Richmond Professional Institute, Richmond, Va, University of Wisconsin Medical School, Madison.

To be eligible for appointment as a Medical Department physical therapy aide on a military status an applicant must have completed two years in an approved college with emphasis on physical education or biologic science, or graduated from an accredited course in nursing, and, in addition to one of the foregoing, completed a training course in physical therapy approved by the Surgeon General. She must be at least 5 feet tall and weigh 105 pounds, must not have passed her 45th birthday, must be a citizen of the United States or of a cobelligerent or friendly country, must meet the physical requirements as prescribed in Army Regulations and have no dependent children under 14 years of age.

Current Army needs are for 1,000 additional trained physical therapy aides. They are being recruited through the Officer Procurement Service, located in each of the nine service commands of the Army and in the large cities.

On Dec 22, 1942 the President signed Public Law No 828, which brought physical therapy aides into the Army on the same basis as Army nurses. Under the act the aides receive an initial issue of clothing, including six regulation white uniforms and caps, a woolen street uniform, woolen cape, shoes, purse and other articles. The only difference in the appearance of Army nurses and physical therapy aides is in the insignia worn. Army nurses have the letter N on the caduceus while physical therapy aides have the letter PT on the caduceus.

NAVY

NEW DISPENSARY HOSPITAL UNITS

The Bureau of Medicine and Surgery of the Navy has announced that new dispensary hospital units have been completed at six auxiliary airfields in Florida each containing ward facilities for 42 patients x-ray equipment complete laboratory facilities flight surgeons instruments examining room and the usual medical surgical and pharmacy facilities. Three medical and two dental officers will be assigned to each unit.

ISLAND NATIVES GIVE TO RED CROSS

Forty-four chiefs and headmen of native tribes on an island in the Solomon Islands have contributed \$194.62 to the American Red Cross the money having been forwarded through the Navy which has a base on the island. The natives have been treated on a voluntary basis in cases of illness or injury by navy medical officers and exhibit a friendly feeling toward America. Lieut F V Best Chaplain Corps USNR Conway SC presented the check for \$194.62 to Mr John Carney director of the American Red Cross for the South Pacific Area.

MEDICAL KITS FOR PATROL BOATS AND SUBMARINE CHASERS

The Medical and Surgical Relief Committee of America 420 Lexington Avenue New York had on August 16 completed the second round of shipments of emergency medical kits to the thirteen naval districts of the Coast Guard for use on patrol boats. The committee has to date distributed three hundred and sixty-two patrol boat sets to the Coast Guard and has donated one hundred and ninety-one similar medical kits to Navy submarine chasers sending them directly to the commanding officer of the individual ships.

The submarine chaser or patrol boat medical kit is a compact case containing essential drugs and instruments and was especially designed by committee physicians to provide emergency treatment to casualties until the ship reaches a base hospital. The kit has proved to be particularly useful when patrol boats pick up shipwreck survivors.

The Medical and Surgical Relief Committee which is celebrating its third birthday is conducted by a nationwide group of physicians for the purpose of sending medical aid to the armed and civilian forces of America and her allies so far the committee has donated \$562,000 worth of medicines vitamins surgical equipment and other supplies to military units needy hospitals, welfare agencies in the war zone and civilian defense posts.

NAVY PROMOTIONS

The following officers have been promoted to captain (MC), USN

Paul T Crosby
Raymond B Storch
Robert E. S. Kelley
Francis B. Brian
Emil J. Stelter
Harry J. Scholtes
Herbert L. Pugh
Oliver A. Smith
Edward P. Kunkel
E. M. Harris Jr.
Winfred P. Danna

Robert M. Gillett
Henry D. Templeton
Dwight F. Wharton
Arthur P. Morton
Harvey E. Robins
John W. Owsley
Arna B. Chesser
Lloyd R. Newhouse
Thomas F. Cooper
Carl M. Dumbauld
Walter F. J. Karbach

The following officers have been promoted to commander (MC), USN

Charles L. Ferguson
Cecil H. Coggins
Walter H. Schwartz
Alfred W. Eyer (detached)

James B. Butler
Charles D. Bell
Alton R. Higgins

POSTHUMOUS AWARD TO LIEUT MILES

The President of the United States on August 5 awarded the Silver Star Medal posthumously to Lieut. (jg) Samuel S. Miles (MC), USNR, for service as set forth in the following citation:

For conspicuous gallantry and intrepidity while attached to Headquarters Company, First Marine Raider Battalion during the attack on enemy Japanese forces on Tulagi, Solomon Islands, on Aug 7, 1942. Knowing that three men of another company had been killed and numerous others wounded Lieut. Miles, with utter disregard for his own personal safety, attempted to cross a zone swept by hostile fire in order to administer first aid to the wounded and isolated men and was killed by the enemy. His great personal valor and heroic devotion to duty were in keeping with the highest traditions of the United States Naval Service. He gallantly gave up his life in the defense of his country.

NAVY PERSONALS

Lieut Comdr Charles F. Gell has reported to the Bureau of Medicine and Surgery and has been assigned for duty to the Bureau of Aeronautics in the Navy Department.

Capt. Fred W. Muller and Lieuts Martin Buehler and Evan C. Stone reported for duty at the Bureau of Medicine and Surgery, Washington, D. C., in June.

Lieut Comdr Charles Wheatley (MC), USN, Ret., has been promoted to the rank of commander on the retired list.

CIVILIAN DEFENSE

SHORT COURSES IN OREGON ON CHEMICAL WARFARE

The Oregon State Medical Society University of Oregon Medical School and Oregon State Defense Council jointly are sponsoring a series of short courses to assist physicians of the state in keeping informed on the latest medical aspects of chemical warfare especially as it pertains to civilians. These courses have been or will be given in Portland Marshfield Salem Eugene and Astoria. Among the subjects of lectures were the symptoms and treatment of lacrimators sternutators systemic poisons and lung irritants and the symptoms physiology pathology and treatment of vesicants. The lecturers were Edward S. West Ph.D. Charles W. Wilson M.D. Charles E. Gurney, M.D., all of the University of Oregon Medical School and Vernon A. Douglas M.D. director of the Emergency Medical Service Oregon State Defense Council. Some of the initial series of these courses have already been finished. The course at Salem was given at 6:30 p.m. July 30 at Eugene August 13 and at Astoria August 20. The course at Portland will be given September 27. Additional information can be obtained from the Oregon State Medical Society Medical-Dental Building, Portland, Oregon.

APPOINTMENT OF NEW REGIONAL MEDICAL OFFICERS

The Office of Civilian Defense Washington D. C. announced on August 9 the appointment of Dr. Harrison A. Walker Miami Beach Fla. as regional medical officer in the Fourth Civilian Defense Region with headquarters in Atlanta to succeed Dr. Burt A. Dyer who is now living in Custer S. D. Dr. Walker graduated from Indiana University School of Medicine in 1917 and later was an instructor in surgery at his alma mater. Since 1925 he has practiced in Florida where he was a member of the surgical staffs of the James M. Jackson Memorial Hospital in Miami and the St. Francis Hospital in Miami Beach.

Dr. Ozro T. Woods Dallas Texas has been appointed regional medical officer of the Eighth Civilian Defense Region to succeed Dr. Witten B. Russ. Dr. Woods graduated from the University of Nebraska College of Medicine in 1924 since which time he has been a member of the faculty of Baylor University School of Medicine in Dallas where since 1928 he has been associated with the Dallas Medical and Surgical Clinic.

UNIFORMS OF U S CADET NURSE CORPS

A Molly Purns wardrobe was selected as the official street uniform of the U S Cadet Nurse Corps by a jury of thirty-two fashion editors of national magazines, newspapers, radio and movies at a luncheon sponsored by the National Nursing Council for War Service at the Waldorf Astoria in New York City on August 16. The winning entrant consists of wool suit,

Maltese cross will be worn on the upper left sleeve of the cadet nurse corps uniform. The Maltese cross, historically associated with the profession of nursing since it was worn by the Knights Hospitalers in the first crusade, is silver against a dark red background.

Assurance that women in essential industries will be released for the United States Cadet Nurse Corps, just as they are for WAC, WAVES, SPARS and Woman Marines, was brought

Insignia of the United States Public Health Service to be worn by members of the U S Cadet Nurse Corps on the beret, the sleeve and the lapel.

top coat, striped cotton summer suit, raincoat and round necked blouses, to be worn with a beret modeled after that of General Montgomery. The basic color is a soft dark gray.

The official insignia of the U S Public Health Service will be worn by the U S Cadet Nurse Corps. The cap device consists of the fouled anchor (denoting distress) of the Navy Medical Corps and the caduceus of the Army Medical Corps, crossed behind the American shield and surmounted by a spread eagle. Buttons and lapel ornaments carry the crossed anchor and caduceus. These insignia were first adopted in 1798. The

the guests by Dr. Parran from the director of the War Manpower Commission. Other guests were Mrs. Frances P. Bolton, Congresswoman from Ohio, Miss Sophie Nelson, vice chairman of the National Nursing Council for War Service, Miss Lucile Petry, director, U S Cadet Nurse Corps, Asst. Surg. Gen. Charles C. Hillman, Army Medical Corps, Mrs. Herbert H. Lehman, Federal Security Agency, Rear Admiral K. C. Mellhorn of the Navy, Col. Florence A. Blanchfield, superintendent of the Army Nurse Corps, and Dr. George Baehr, chief medical officer, Office of Civilian Defense.

FREE TRAINING FOR NURSES

Allotments totaling \$836,461 to six nursing schools offering free nurse training in conjunction with the program of the U S Cadet Nurse Corps were approved on August 16 by Dr. Thomas Parran, Surgeon General, U S Public Health Service. The funds will be used to accelerate the training of nurses for essential civilian and military service during the war emergency. Students receive tuition, fees, stipends and uniforms from these allocations.

The schools to which funds were allotted include:

Children's Hospital School of Nursing, Boston, \$44,960, affecting about 64 nurses in training and 25 to enroll.

Bridgeport Hospital School of Nursing, Bridgeport, Conn., \$88,436, affecting about 80 nurses in training and 80 to enroll.

Christ Hospital School of Nursing, Cincinnati, \$144,068, affecting about 124 nurses in training and 128 to enroll.

Highland School of Nursing, Oakland, Calif., \$161,754, affecting about 171 nurses in training and 80 to enroll.

Presentation School of Nursing in four units with headquarters at Aberdeen, S. D., and units at Sioux Falls and Mitchell, also in South Dakota and Miles City, Mont., \$280,459, affecting about 278 nurses in training and 115 to enroll.

Cook County School of Nursing, Chicago, \$116,784, affecting about 96 nurses in training and 130 to enroll.

The program of the United States Cadet Nurse Corps was approved at the last session of Congress, and its objective is to enroll 65,000 student nurses immediately.

CEILING PRICES FOR SYNTHETIC RUBBER DRUG SUNDRIES

As hot water bottles and combination syringes made of synthetic rubber for use in hospitals have been coming on the retail market for the first time, the Office of Price Administration on August 12 gave them retail selling prices in line with the prewar prices for the same grade when made of crude rubber.

Today's maximum retail price for the Victory line hospital grade molded hot water bottles made of synthetic rubber is \$1.30, retail ceilings for two lower grades, which were in the regulation already, are \$1 and 75 cents respectively. The retail ceilings for three types of the Victory line hospital grade combination syringes range from \$1.65 to \$2.20. Combination syringes of the lower grade, already priced in the regulation, range from \$1.10 to \$1.90. No price increase is represented by the ceilings set for the hospital grade on sales in the retail market because they are at the same level that existed before the war for sales of the same grade when made of crude rubber; these prices have always been above those for hot water bottles and combination syringes of lower grades. The hospital grade is made to more stringent specifications and is more durable than those grades not made especially for use in hospitals.

This amendment became effective on August 19.

ORGANIZATION SECTION

OFFICIAL NOTES

WAR PARTICIPATION COMMITTEE

Meeting held in Washington, D C, July 30-31

Present Members Drs Edward R Cunniffe, Walter F Donaldson chairman, Morris Fishbein, William R Molony and James E Paullin, also Dr Roscoe L Schenck and Lieut Col Harold C. Luth

Questions introduced for discussion were

Are present methods of obtaining medical personnel the best that can be devised?

The Procurement and Assignment Service for Physicians, Dentists and Veterinarians is in need of aid in securing replacements in civilian areas

Since it is reported that some 1600 physicians have been discharged from the armed forces are present methods of utilizing physicians discharged from the service satisfactory?

What will be the effect of the present Army and Navy specialized training program on the future of medical education?

Is the Army utilizing physicians to the best advantage?

It was decided that the latter two questions should be introduced at the joint session with the Directing Board of Procurement and Assignment Service and the Surgeon Generals of the Army, Navy and Public Health Service also a request for clarification of the order covering men between the ages of 38 to 44 recently issued by the Adjutant General's Office

Other questions to be raised were agreed on as follows

A What pressures may be agreed on toward encouraging recruitment of medical officers?

B What are the current standards of 'essentiality and availability'?

C Can recruitment be encouraged by further modifying the physical requirements?

D Is there any hope of gaining additional recruits through physical rehabilitation?

E What is the status of men now classified as 'essential in research'?

Formal action was taken by which the War Participation Committee requests the Board of Trustees of the American Medical Association to recommend to the Association's Postwar Planning Committee the development of plans for (1) continuing education including internship residencies and refresher courses for physicians discharged from the armed forces also (2) consideration to be given to the relocation of physicians emerging from the armed forces and such other aid as may be given to ex-service physicians on request It was suggested that the Postwar Planning Committee submit its program for these purposes to the next meeting of the House of Delegates

Subsequently the committee also decided to submit to the Board of Trustees of the American Medical Association for appropriate action the following

That the American Medical Association ask the state and local medical societies to cooperate with the Procurement and Assignment Service in carrying out its obligations to the armed forces and the civilian population in procuring more physicians for the armed forces and effecting a better distribution of physicians

That the Board of Trustees of the American Medical Association utilize the activities of that association such as THE JOURNAL and other divisions in this program

The committee met at 9 a m at the Hotel Statler Present were Drs Edward R Cunniffe, Walter F Donaldson chairman, Morris Fishbein, Roger I Lee, William B Molony and Olin West

The committee reviewed the agenda that had been prepared at the session of the previous evening and approved its presentation to the Directing Board of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians

Following extended discussion the committee adjourned to meet at 11 a m with the Directing Board of the Procurement

and Assignment Service and with representatives of the Offices of the Surgeon Generals of the Army, Navy and Public Health Service, and the Officer Procurement Service in the New Social Security Building

The War Participation Committee offered the full cooperation of the American Medical Association in aiding the procurement of some 5,000 to 6,000 additional physicians required to meet quotas up to Jan 1 1944 Ways and means were discussed for aiding the recruitment of physicians in various areas

During the afternoon joint session a statement was made by the Hon Paul V McNutt, chairman of the War Manpower Commission relative to the needs for physicians Mr McNutt expressed his appreciation of the work of the Directing Board of the Procurement and Assignment Service and of the American Medical Association He felt that the medical profession was the only group authorized to conduct its own recruitment and the safeguarding of professional services in civilian life and that the task had been well done He discussed also proposals for aiding the procurement of physicians during the remainder of the year as well as many of the questions prepared by the Committee on War Participation

OBSTETRIC AND PEDIATRIC CARE FOR WIVES AND CHILDREN OF ENLISTED MEN

[See editorial this issue page 1251]

[Letter sent by Dr George H Kress, secretary-editor, California Medical Association, Aug 6, 1943]

Dear Doctor West

We continue to be much interested in the Federal Children's Bureau Plan

We have noted the following articles in THE JOURNAL

Maternity Care for Wives of Enlisted Men THE JOURNAL July 17 p 816
Daily E F Medical and Hospital Maternity and Infant Care *ibid* July 31 p 945

I am writing to ask if any other articles appeared in THE JOURNAL on the subject, and if so, will you kindly send me the references?

Thanking you for your prompt attention to this,

Cordially yours,

GEORGE H KRESS, M D, San Francisco

[Reply of Dr Olin West, Secretary, American Medical Association sent August 10]

Dear Doctor Kress

Your letter of August 6 was received on August 9, since which time I have had prepared a list of references to items pertaining to obstetric and pediatric care for the wives and children of service men that have appeared in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

I presume you know that the program of the Children's Bureau for providing obstetric service was initiated in the state of Washington in 1941 and was extended to other states beginning in August 1942

In the Federal Legislative Bulletin No 19 of our Bureau of Legal Medicine and Legislation, dated Sept 1 1942, there was a three page discussion of legislation introduced at the request of the President of the United States proposing an additional appropriation for the Children's Bureau Part of this appropriation was to be used to provide maternity services for the wives of service men This bulletin was sent to the officers of all state medical associations

On page 47 of THE JOURNAL for Sept 5 1942 there appeared an editorial comment on the two bills that had been introduced at the request of the President It was pointed out in the editorial comment that part of the appropriation provided for in the bills was to be used for maternity care for the wives of service men In the same issue of THE JOURNAL, on page 55,

there was a brief reference to the introduction of these two bills, neither of which was enacted

In *THE JOURNAL* for Nov 14, 1942 on page 846 there was an item under the title "Medical Care for Wives and Infants of Men in Military Service" in which reference was made to the program of the Children's Bureau and to the fact that funds had been set aside by the bureau from its appropriation for the fiscal year 1943 in the amount of \$198,000

In *THE JOURNAL* for Nov 21, 1942 on page 974 there was a news item descriptive of the plan being put into operation in the state of Missouri for providing medical and hospital obstetric and pediatric care for the families of men serving in the armed forces

On page 603 of *THE JOURNAL* for Feb 20, 1943 reference was made to a supplemental estimate that had been submitted to the Seventy-Seventh Congress by the President asking for an appropriation of \$1,200,000 to be used by the Children's Bureau in making grants to states to provide medical, nursing and hospital maternity and infant care for wives and babies of enlisted men of certain grades serving in the armed forces. In the Federal Legislative Bulletin No 25, dated March 1, 1943 reference was made to this supplemental estimate that had been submitted to Congress and to the fact that the House Committee on Appropriations had refused to include the estimate in the deficiency appropriation bill, H R 1975

On page 872 of *THE JOURNAL* for March 13, 1943 reference was made to a bill introduced by Representative Keefe, H R 2041, proposing to authorize an appropriation of \$6,000,000 for each fiscal year during the war and for six months thereafter to provide obstetric and pediatric care for the wives and infants of service men. This bill, as I am informed, is still in the hands of the House Committee on Education and Labor

In the Federal Legislative Bulletin No 25, dated April 5, 1943 reference was made to the fact that when the deficiency appropriation bill, H R 1975, came before the Senate for consideration there was included in the bill the appropriation requested by the President, and that the House thereafter agreed to this appropriation and the President signed the bill. In this same issue of the Bulletin reference was made to the bill introduced by Representative Keefe

On page 1231 of *THE JOURNAL* for April 10, 1943 there was an item under the heading "Medical Care for the Wives and Children of Enlisted Men" which referred to the appropriation of \$1,200,000 that had been made available for obstetric and pediatric services, to the regulations that had been promulgated by the Department of Labor under date of March 26 for the allotment of this money and to the nature of the testimony given by the chief of the Children's Bureau before a subcommittee of the House Committee on Appropriations in support of the request for the appropriation

On page 1379 of *THE JOURNAL* for April 24, 1943 there appeared in the Report of the Board of Trustees a reference to the federal program here under discussion

On page 382 of *THE JOURNAL* for June 5, 1943 there was an item under the title "Maternity Care for Wives of Certain Grades of Enlisted Men" summarizing the extent to which the plan had been put into operation

There appeared in *THE JOURNAL* for June 26, 1943 on page 628 a reference to H R 2935, the Labor Department-Federal Security Agency appropriation bill for the fiscal year ending June 30, 1944, which contained at that time provision for the appropriation of \$4,000,000 for the use of the Children's Bureau in carrying out the program under discussion. This sum was increased before the appropriation bill was enacted to \$4,400,000

On page 621 of the same issue of *THE JOURNAL* reference was made to the action taken by the House of Delegates of the American Medical Association in approving generally the action of the federal government in making funds available for maternity and infant care for the wives and infants of enlisted men but recommending that allotments be paid directly to the wives

In the Federal Legislative Bulletin No 28 under date of July 15, 1943 reference was made to the enactment of the Labor Department-Federal Security Agency appropriation bill authorizing the appropriation of \$4,400,000 for grants to states to provide obstetric and pediatric care

On page 816 of *THE JOURNAL* for July 17, 1943 there appeared a statement which was in the nature of a summary of the report issued by the Secretary of Labor on the progress made in the several states in carrying out the program of the Children's Bureau

In *THE JOURNAL* for July 31, 1943, beginning on page 945, there appeared a special article by Dr Edwin F Daily, director of the Division of Health Services of the Children's Bureau

There have been other references in special legislative bulletins sent to all state medical associations by our Bureau of Legal Medicine and Legislation pertaining to the proviso

included in the appropriations bill H R 2935 which places certain restrictions on the Children's Bureau

There seems to have developed an impression on the part of many that the plans of the Children's Bureau for providing obstetric and pediatric services for the wives and infants of enlisted men were not initiated until March 18, 1943, on which date the President signed the deficiency appropriation bill in which was included provision for the appropriation of \$1,200,000 to finance the program of the Children's Bureau for the remainder of the fiscal year. The fact is that the program of the Children's Bureau was initiated in 1941 after the department of health of the state of Washington had petitioned the Children's Bureau for financial assistance to help in providing obstetric and pediatric service for the wives and children of enlisted men stationed at Fort Lewis. That was the first project started, and no other similar project was put into operation until August 1942. In the time between August 1942 and February 1943, programs quite similar to the one initiated in the state of Washington became effective in twenty-seven states, and the Children's Bureau made available the sum of \$390,177 to be used in financing the programs in those states. These funds were set aside by the bureau from the regular appropriation authorized for maternal and child health services under part 1 of title V of the Social Security Act. Our information is to the effect that other states than the twenty-seven referred to made application for funds to be similarly used, which could not be granted because the bureau had no additional funds available

In view of the fact that at least twenty-seven states collaborated in the program of the Children's Bureau over a considerable period of time, it is a little surprising that no state medical association found the program so objectionable as to induce the filing of any complaints with the American Medical Association. I have heard that the program was approved in some states, though I have no official advices to that effect. However, articles appeared in some state medical journals that were entirely favorable to the bureau program. In the *Journal of the Medical Society of New Jersey* for November 1942 there appeared a two page statement in which it was stated that the Medical Society of New Jersey had agreed to participate in the program and the reasons for that decision were given. A somewhat similar statement appeared in the *Journal of the Missouri State Medical Association* for November 1942

I presume that by this time you have received a release from our Bureau of Legal Medicine and Legislation pertaining to the opinion of the Attorney General of the United States with respect to the effect of the provisos that were included in the appropriation bill for the Department of Labor, of which the Children's Bureau is a part

It will no doubt interest you to know that I had a visit a few days ago from the health officer of one of our larger Middle West states, who stated that applications for obstetric and pediatric service for the wives and children of soldiers were coming into his office at the rate of one thousand a month and that the tentative estimate indicated that the cost of such service in that one state under the Children's Bureau program probably would amount to \$1,250,000 a year. In that particular state, I understand, the fee for obstetric service including antepartum and postpartum care will be fixed at \$45. Our visitor made a very interesting point when he stated that in many if not in most instances the wives of soldiers demand that they have the services of the best qualified obstetricians, who are already overwhelmed with work, and he expressed a fear that the obstetricians would be put in a bad light if they refused to serve the wives of soldiers under the Children's Bureau-State Health Department program even though their own private practice demanded every minute of their time

If this service is to cost a million and a quarter in one state, the appropriation of \$4,400,000 will be exhausted very rapidly

With most cordial good wishes, I am

Very sincerely yours,
OLIN WEST

[Letter from Dr George H Kress, secretary-editor, California Medical Association, sent Aug 17, 1943]

Dear Doctor West

Many thanks for your courtesy in sending to me your letter of August 10 with its information concerning references in *THE JOURNAL* on maternity-pediatric care

The letter was received too late to be of use in my August editorials for *California and Western Medicine*

I am very glad to have this information for our files

Cordially yours,
GEORGE H KRESS, M D, Secretary-Editor

Medical News

(PHYSICIANS WILL CO-OPERATE BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

COLORADO

First Case of Typhus—On July 3 a Denver physician reported a case of typhus. According to the Colorado State Board of Health *Bulletin* this is the first instance on record in which typhus has occurred in Colorado. The patient was a man who has been a long time resident of Denver with a history of not leaving the city for a considerable period of time.

University News—Dr Lloyd J Florio, associate professor of public health and laboratory diagnosis, University of Colorado School of Medicine, Denver, has been granted a leave of absence to study tropical medicine in Central America under a grant from the Markle Foundation. Newspapers reported on June 2 Dr John M Lyon and Robert W Davis have been appointed assistant professors of psychiatry at the school and Dr Merrill C Jobe named assistant professor of surgery, all of Denver.

FLORIDA

Annual Graduate Course—The eleventh annual graduate short course for physicians was held in Jacksonville, June 21-26 under the auspices of the state medical association. The instructors were:

Dr Robert W Wilkins, Boston, Medicine
Dr Milton Ochsenr, New Orleans, Surgery
Dr Samuel F Ravenel, Greenboro, N. C., Pediatrics
Dr M. Pierce Beecher, Richmond, Va., Obstetrics
Dr Clayton T. Beecham, Philadelphia, Gynecology
Dr Austin A. Deibert, Hot Springs, National Park, Ark., Venereal Diseases

IDAHO

Hospital News—Plans are being considered to turn over to the Army and Navy the partly completed state tuberculosis hospital at Gooding.

State Medical Meeting—The fifty-first annual meeting of the Idaho State Medical Association will be held at the Owyhee Hotel, Boise, August 30-31. The tentative program includes the following speakers:

Lieut. Col. Frank B. Queen, National Guard, Penicillin Laboratory, Diagnosis of Tropical Diseases
Lieut. Col. James S. Sweeney, M. C. A. U. S., Clinical Interpretation of Blood Pressure, Peptic Ulcer Syndrome
Lieut. Col. Henry G. Hollenberg, M. C. A. U. S., Recent Advances in Vascular Surgery, The Acute Surgical Abdomen
Major Max T. C. Schnitzer, M. C. A. U. S., Diagnosis and Treatment of Acute Head Injuries and Peripheral Injuries
Major Ernest E. Myers, M. C. A. U. S., Pitfalls in Treatment of Fractures, Amputations
Lieut. Col. Oliver B. Chamberlain, M. C. A. U. S., Concepts of Psychosomatic Medicine, Acute Episodes, Simulating Psychoses

ILLINOIS

New Species of Mosquito Found in State—Among more than 200,000 mosquitoes collected and identified by sanitary engineers and entomologists connected with Illinois projects for malaria control in war areas there were found four species that had never been known to exist in the state. According to the *Illinois Health Messenger*, among them was *Aedes aegypti*, the species that transmits yellow fever.

Chicago

Course in Otolaryngology—The department of otolaryngology of the University of Illinois College of Medicine will conduct the second of its series of short refresher courses the program to include one week of didactic instruction, September 27-October 2, and three days of clinical conferences, October 4-6. The fee for the course will be \$50. Registration will be by application through the department of otolaryngology at the medical school.

Grant for Research in Penicillin—The Schenley Distillers Corporation through its president Louis Rosenstiel has made available to Northwestern University Medical School a grant for research on penicillin to include the production of the product and its application in cases of disease. A special

committee has been established to control this research. The committee includes Chester J. Farmer, M. A., chairman, Dr Alexander A. Day, Dr Sumner L. Koch, Dr Walter S. Priest, Henry B. Bull, Ph.D., Dr Guy P. Youmans and Mr Samuel E. Thomson.

New Pharmacology Department at Loyola—With the appointment of Dr Amedeo S. Marrazzi, assistant professor of pharmacology, New York University College of Medicine, effective September 1, as professor and head of the department of pharmacology, a new pharmacologic unit will be launched at Loyola University School of Medicine. Pharmacology and the department of physiology have been operating under the direction of Dr Theodore Boyd, who under the new arrangement will continue as professor and head of the department of physiology. Dr Edward Piszczek, health commissioner of Cook County, has been made acting chairman of the department of bacteriology and public health.

KANSAS

Personal—Dr Samuel A. Mallison, El Dorado, has resigned as health officer of Butler County to become superintendent of the Southern Illinois Health District with offices in Harrisburg, Ill.—Dr William T. Grove, Eureka, has been appointed health officer of Greenwood County to succeed Dr Walter S. Moonlight. Eureka resigned.—Dr Charles W. Jones, Olathe, has been appointed a member of the state board of medical registration and examination to succeed Dr James E. Hanshall Osborne.

Courses on Lung Disease—On August 28 a postgraduate course in lung disease will start in Kansas City under the auspices of the University of Kansas School of Medicine, Lawrence-Kansas City, the state board of health, the Kansas Tuberculosis and Health Association and the state medical society. The program will be offered in Parsons on August 30, Wichita September 1, Salina September 2 and Emporia September 4. Three sessions will be held in each town. Drs Carl C. Birkelo, Detroit, and Henry C. Sweany, Chicago, will be the instructors.

KENTUCKY

Rocky Mountain Spotted Fever—One death from Rocky Mountain spotted fever occurred in Bracken County early in August, newspapers report. In the last three years 3 cases of the disease have appeared in the county, all in children, 2 of which were fatal.

LOUISIANA

Dr Trufant III Wins Walter Reed Award—Dr Samuel Adams Trufant III, who graduated this year at the Tulane University of Louisiana School of Medicine, New Orleans, has been presented with the Walter Reed Memorial Award for his thesis entitled 'Sylvatic Plague'. The award is given by the Louisiana State Medical Society to a senior student at Tulane or the University of Louisiana School of Medicine. Ultimately a medal will signify the award but thus far, since the first presentation in 1942, the prize has been represented by a certificate of award.

Dr Duncan Named Professor of Anatomy—Donald Duncan, Ph.D., professor and head of the department of anatomy at the University of Buffalo School of Medicine, Buffalo, has been appointed professor of anatomy at Louisiana State University School of Medicine, New Orleans. Dr Duncan received his Ph.D. at the University of Minnesota, Minneapolis, in 1929. Later he served for a time at the University of Utah, Salt Lake, as assistant professor of anatomy and at the University of Texas Medical Branch, Galveston, as associate professor of anatomy. His appointment to the Louisiana faculty will take effect on October 1.

MAINE

Personal—Dr Emanuel Levy, chief of the medical service of the Veterans Administration Facility, Bronx, N. Y., has been appointed chief medical officer at the Veterans Administration Facility in Togus.

Medicolegal Officers Named—New officers of the Maine Medico-Legal Society, elected at the annual meeting in Augusta, June 20, are Dr Delbert M. Stewart, South Paris, president; Benjamin Butler Farmington, vice president; Dr George L. Pratt, Farmington, secretary; and Dr Walter S. Sturichfield, Skowhegan, treasurer.

MASSACHUSETTS

Bequest for Hospital Laboratories—Brooks Hospital, Brookline, will receive \$300,000 and the residue of the estate for the maintenance of its laboratories through a provision in the will of the late Miss Alice E. Sias, Boston. The hospital will also receive \$25,000 for general use. The bequest for the laboratories, which were established by Mrs. Sias several years ago as a memorial to her husband, will be set up in a trust fund.

Dr. Hale Retires at Harvard—Dr. William Worth Hale, since 1918 associate professor of pharmacology and assistant dean of the faculty of medicine, Harvard University, Boston, will retire from his teaching activities at the university on August 31. Dr. Hale, who graduated at the University of Michigan Medical School, Ann Arbor, in 1904, served for a time as assistant surgeon with the Granite Mining Hospital, Montana, assistant in pharmacology at the University of Michigan and from 1908 to 1913 as assistant pharmacologist with the U. S. Public Health Service. He joined the faculty of medicine at Harvard in 1913 as assistant professor of pharmacology. He will continue as assistant dean of the faculty of medicine and chairman of the committee on admissions. This spring students of the graduating class dedicated their yearbook "The 1943 Aesculapiad" to Dr. Hale.

MICHIGAN

Chapter of Soviet Medical Society—The Detroit chapter of the American-Soviet Medical Society was launched at a meeting, August 18, at which Dr. Vladimir V. Lebedenko of the department of surgery, First Moscow Medical Institute, was the principal speaker, discussing his experiences with Soviet war medicine. Dr. Warren B. Cooksey, head of the Michigan Blood Bank, presided. The American-Soviet Medical Society was recently organized to stimulate the exchange of medical information between the United States and the Soviet Union (THE JOURNAL, June 12, p. 457).

Society Asked to Curb Advertising Clinics—A drive to stamp out advertising clinics, sanatoriums and such like which profess to be able to "cure everything, but which in reality are nothing but unadulterated fakers," was announced on July 3 by George F. Addes, secretary-treasurer of the U. A. W.-C. I. O. and director of its medical research, health and accident department, according to the Detroit News. In letters to the Michigan State Medical Society and the Wayne County Medical Society, Addes asked that they make investigations and "take immediate steps to stop the many trick devices that are being used to lure money away from the workers through false pretenses."

NEW JERSEY

Dr. Vail Observes Ninety-Eighth Birthday—Dr. William H. Vail, Newark, the oldest living alumnus of Princeton University, celebrated his ninety-eighth birthday, August 4. Recently the university took title to the house occupied by Dr. Vail so that he could live there "as long as he may desire" (THE JOURNAL, June 19, p. 552). Dr. Vail, who was a member of Princeton's class of 1865, is also said to be the oldest living alumnus of the College of Physicians and Surgeons of Columbia College, New York, where he graduated in 1869.

NEW YORK

Personal—Dr. Richard Nauen, senior tuberculosis physician of the New York State Hospital, Ray Brook, has been appointed tuberculosis control director of Cattaraugus County and superintendent of the county sanatorium.—Dr. Nicholas J. Colao, Peekskill, was chosen president of the city board of education, July 6, for the ensuing year.

New York City

Venereal Disease Activities—The bureau of social hygiene of the New York City Department of Health now has facilities for darkfield examinations for syphilis at seventeen social hygiene diagnostic centers. The service is offered without charge to physicians to aid in the diagnosis of early syphilis. New York physicians are eligible for the clinical refresher course in modern methods of diagnosis and treatment of venereal disease conducted during the summer at the city department of health under the direction of Dr. Louis Chargin. The bureau of social hygiene is also making available a number of pamphlets designed to keep the general practitioner up to date on modern methods of the diagnosis and treatment of venereal diseases.

Graduate Courses in Neurology and Psychiatry—Graduate courses are offered in neurology and psychiatry by Columbia University College of Physicians and Surgeons and cooperating institutes, beginning October 4 and ending December 10. These courses are designed for physicians interested in neurology and psychiatry. In addition to the clinical survey, they aim to cover, in part, the sociological and educational fields. Among these sources of clinical material are the psychiatric and neurologic outpatient departments of the Vanderbilt Clinic, the Psychiatric Institute and Hospital and the Neurological Institute of New York. The courses consist of lectures, laboratory work, demonstrations and practical clinical courses. Any individual course (except clinical assignments in neurology and psychiatry) may be taken singly. Arrangements may be made for an extensive course in neuropathology. The major part of the time is spent in practical laboratory work in the department of neuropathology of the psychiatric institute. Information may be obtained by applying to the Dean of the Faculty of Medicine, Columbia University, 630 West 168th Street, New York 32.

NORTH DAKOTA

Changes in State Health Department—Dr. Mary E. W. Soules, assistant director of maternal and child hygiene for the North Dakota State Department of Public Health, Bismarck, has been named director, effective August 1, to succeed Dr. Robert G. White, who has been appointed director of the Burke-Minot-Ward district health unit. Dr. George F. Campana, formerly assistant district state health officer in New York, and recently of Albany, N. Y., has been appointed state epidemiologist and director of the division of preventable diseases for North Dakota.

OREGON

State Medical Meeting—The Oregon State Medical Society will conduct its annual meeting at the University of Oregon Medical School, Portland, September 4-5. The banquet will be in the Benson Hotel, Sunday evening. Many officers from the armed services will participate in the program, which will cover tropical medicine, industrial medicine and military medicine for civilian and combat areas.

SOUTH CAROLINA

Refresher Course—The Medical College of the State of South Carolina, Charleston, will conduct a refresher course for practicing physicians, November 3-4. The program was inaugurated last year at the request of alumni. Those participating in the course will include Drs. Leroy U. Gardner, Saratoga Lake, N. Y., Alfred Blalock, Baltimore, Roy R. Kracke, Emory University, Ga., Charles Christian Wolferth, Philadelphia, Virgil P. W. Sydenstricker, Augusta, Ga., John Theodore King, Colonel, M. C. A. U. S., Harrison F. Flippin, Philadelphia, and George W. Thorn, Boston.

Dr. Boozer Resigns as Secretary of State Board—Dr. Albert E. Boozer, Columbia, has resigned as secretary of the South Carolina State Board of Medical Examiners, a position he has held since 1911. He has been a member since 1909. The board recently adopted a resolution acknowledging his able services. Dr. Nathaniel B. Hevvard, Columbia, is the new secretary of the board. Dr. Boozer graduated at the University of Pennsylvania School of Medicine, Philadelphia, in 1892. He began private practice in Columbia the same year and was on the first board of physicians of Columbia Hospital. A few years ago he resigned as medical director and examiner for the Carolina Life Insurance Company, a position he held for about twenty years. According to the state medical journal, Dr. Boozer was assistant medical referee with the Mutual Life Insurance Company and the medical referee of the Missouri Life Insurance Company, serving as examiner for twenty-five other life insurance companies.

TEXAS

Community Honors Physician—Dr. Thomas E. Winford, Dallas, was presented with the W. H. Adamson child welfare trophy for 1943 on July 13. The award, which is given annually to the person in Oak Cliff adjudged to have done the most child welfare work during the previous year, went to Dr. Winford for his work for underprivileged children in the free eye, ear, nose and throat clinic operated at the Dallas Methodist Hospital under the auspices of the Oak Cliff Lions' Club.

Physician Sentenced for Draft Evasion—Federal Judge T. Whitfield Davidson overruled a motion for a suspended sentence for Dr. Lawrence E. Arnold, Dallas, who is under a two-year sentence for draft evasion, newspapers reported. It was

stated that the superintendent of a local hospital and numerous physicians joined in the plea for a suspended sentence because of the service that Dr. Arnold has been performing in treating patients since his sentence and since the departure of so many of the local physicians for the armed services.

WEST VIRGINIA

New Education Plan Begins at West Virginia University—The fall term of the West Virginia University School of Medicine is scheduled to start September 27 and end December 17. Twenty-five sophomore students, including two women, will complete their work at the end of the term. Of this number, twenty will immediately transfer to the Medical College of Virginia, Richmond, under the provisions of the medical education plan recently agreed to by both schools (*THE JOURNAL*, March 13, p. 877). The other five members of the class have been accepted at the medical schools of the University of Pennsylvania, University of Cincinnati, Temple University and Jefferson Medical College.

WISCONSIN

Found Guilty of Improperly Using Title "Doctor"—Fred Neukom, 63 Winona, Minn., was freed of a charge of practicing medicine without a license in the state of Wisconsin but was found guilty of improperly using the title "doctor" by a municipal court jury in Racine on June 4. According to the *Wisconsin Medical Journal*, the charge under which Mr. Neukom was tried was brought as the result of a complaint signed by an investigator for the state board of medical examiners, who had testified that he had been treated by Mr. Neukom on January 27.

Advisory Committee Named to Study Problems of State Institutions—At the request of the state board of public welfare, Dr. Russell M. Kurtin, Racine, president of the State Medical Society of Wisconsin, appointed an advisory committee to meet with the board members and study existing problems and policies affecting the state institutions. The new advisory committee made up of Drs. Horace Kent, Tenney, Jr., and Henry L. Greene, Madison; Elwood W. Mason, and John L. Garvey, Milwaukee; and Wayne A. Munn, Janesville, held its first session on June 24 in Union Grove.

Personal—Dr. Albert Popp, Milwaukee, has been appointed a police physician and surgeon, succeeding the late Dr. David D. Mehigan. Dr. Edward P. Evans, Milwaukee, was guest of honor at a luncheon recently marking his retirement as medical examiner of the Equitable Life Assurance Society of the United States after eighteen years in the position. Dr. Erwin C. Cary, Reedsville, has been reappointed health officer for the village of Reedsville and also for the towns of Rockland and Franklin. He was recently reelected president of the Manitowoc County Health Officers' Association.

Waukesha Springs Sanitarium Ends Service—The recent retirement of Dr. Byron M. Caples as head of the Waukesha Springs Sanitarium and the sale of part of the sanatorium property to Carroll College, Waukesha, marks the end of the operation of the institution. The sanatorium was established by Dr. Caples in 1898. He plans to continue his practice in Waukesha and to run a 30-acre farm on the outskirts of the city. The transfer of the property to Carroll College was brought about when the college experienced a housing shortage after cadets of the army air corps had been assigned to the college.

GENERAL

Reprints on Psychosomatic Medicine and Psychiatry Available—The Josiah Macy, Jr. Foundation, New York, has made it possible for the National Committee for Mental Hygiene to distribute a limited number of reproductions or reprints of selected scientific articles bearing on war problems in the field of psychosomatic medicine and psychiatry to medical officers in the armed forces of the United Nations. Medical officers who wish to receive such articles should notify the National Committee for Mental Hygiene, 1790 Broadway, New York 19.

Chinese Medical Journal Resumes Publication—The *Chinese Medical Journal*, which suspended publication when the Japanese took over the offices of the Chinese Medical Association in Peking in December 1941, is now being issued at P. O. Box 6096, Washington, D. C., as a quarterly since printing and circulation facilities in Free China are inadequate. However, the medical profession in China still has its Chinese edition. The publication of the journal in the United States has been made possible by the assistance of the Chinese Foundation.

Microfilm and Slide Hand Viewer—A hand viewer for reading, strip films and viewing 2 by 2 slides is now in production and will be on the market within a few weeks. This viewer was designed especially for the use of the medical services of the armed forces through the efforts of the Army Medical Library. Full information with regard to obtaining the viewer, which magnifies approximately ten times and which is definitely in the low price class, will be supplied on request by addressing the Photoduplication Service, Army Medical Library, 7th and Independence Avenue S.W., Washington 25, D. C.

Eye Health and Safety News—The National Society for the Prevention of Blindness is now publishing a bimonthly newsletter entitled *Eye Health and Safety News* for free distribution among physicians, nurses, public health officials, social workers, educators, safety engineers, and others who are professionally interested in some aspect of sight conservation. Each issue of the *News* contains items on developments and new projects in the campaign for prevention of blindness. A regular feature is the reporting of activities in this field carried on by official voluntary state agencies. Those who are interested in receiving this new publication regularly are invited to write to the society, 1790 Broadway, New York 19.

Conference on Tuberculosis—The Mississippi Valley Conference on Tuberculosis and the Mississippi Valley Trudeau Society will hold their thirtieth annual meeting at the Edgewater Beach Hotel, Chicago, September 8-9 under the presidencies of Dr. Charles H. Lerrigo, Topeka, Kan., and Dr. Frank L. Jennings, Indianapolis, respectively. In addition to general sessions, there will be discussions on health education, war problems, rehabilitation and an x-ray conference. Among the speakers will be:

Dr. George F. Parker, Greencastle, Ind., College Health Services and the War
Clarence M. Sharp, surgeon, U. S. Public Health Service Reserve
Belthe da Vid, Examination of Industrial Workers
Dr. Adolph G. Kammer, Chicago, Tuberculosis in Industry
Dr. Everett K. Geer, St. Paul, Transient Infiltration of the Lung
Parenchyma Associated with Eosinophilia
Lieut. Comdr. Horatio B. Sweetser, Jr. (MC), U. S. Naval Reserve
Rheumatic Fever in Young Adults
Lieut. Col. Esmond R. Loug, M. R. C., The Discovery and Disposition of Cases of Tuberculosis in the Army or the United States

LATIN AMERICA

The Hospital Infantil—The first children's hospital built by the Mexican government was dedicated in Mexico City on May 29. The second hospital to be completed in the new medical center now under construction, the unit will be used as a teaching hospital for the medical school of the National University and has lecture rooms, class rooms and student laboratories located in the building. Of concrete construction, the building has six floors with a capacity of 550 beds for children of all ages from newborn infants up to 14 years of age. Facilities and services of the hospital include an outpatient clinic with adjoining laboratories for special diagnostic services, inpatient facilities for pediatrics, orthopedic surgery, general surgery, otolaryngology, ophthalmology, neurology and dermatology services, as well as special provisions for physical therapy, occupational therapy and educational and social services. One unit has been specially designed for the care of premature infants. There are also a breast milk station and a well equipped milk laboratory. The department of nutrition, which is responsible for the preparation of food for child patients and employees, is staffed by persons trained in dietetics and is furnished with mechanical refrigerators and other modern equipment. Experienced educational therapy workers will teach invalid or crippled children occupations that they will be able to continue after leaving the hospital, instruct them in their school subjects so that they need not fall behind and help them in other ways to spend the time in the hospital usefully and pleasantly. Dr. Federico Gomez, Mexico City, is in charge of the hospital and Dr. Juan Farill has been named chief of the orthopedic service.

CORRECTION

Academy of Medicine Receives Endowments—In a news item the *THE JOURNAL*, July 31, page 959, announcing the creation of an endowment in perpetuity at the New York Academy of Medicine by R. Thornton Wilson in honor of his wife, the name should have been Frances Elizabeth Wilson and not Frances Elizabeth Wilson.

Science and the State

The necessities of war have led to science playing a more important part in national affairs than ever before. In a letter to the *Times* three leading scientists, R. H. Pickard, chairman of the Joint Council of Industrial Scientists, Alexander Findlay, president of the Royal Institute of Chemistry, and Prof. W. L. Bragg, president of the Institute of Physics, endorse the pleas now being made that scientific effort, so effective in the war, shall not be allowed to cease when peace returns but shall be applied to the problems of reconstruction. They object, however, to the exaggerations of many responsible scientists which often accompany reasonable claims. It is sometimes said that if some fraction of the national income was allocated to scientific research and if scientists were given a position of authority in the state, we would find ourselves in "an age of plenty." Such misleading of the community as to its resources can only foster illusions and bring disappointment. While we may hope that the improvement in our material comforts, which has marked the past fifty years, will be continued, it should be remembered that the fruits of research sometimes ripen slowly and that our material resources during the postwar period cannot be vastly greater than those we now possess.

The claim that the scientist as such is entitled to some position of exceptional authority in deciding the policies of governments is one which cannot be accepted in a democratic community. Social problems are too complex to be solved by any one type of mind. But the scientist can give valuable help in solving problems and could profitably be consulted more frequently. No social problem can be solved solely by the methods of science, for other values are involved than material ones.

Armored Vests for American Airmen

Armored vests to protect the crews of bombers of the United States Eighth Air Force against flak splinters and fragments of explosive shells have been designed and manufactured in England. They have already been worn in several raids and the results are regarded as extremely satisfactory. The vest is made of canvas on which are sewn squares of manganese steel so that they overlap slightly, giving complete protection to the chest and the back. An apron section, suspended from the vest by hooks, is also worn, giving cover as far as the knees. The vest and apron are made in two types, full width for men whose duties cause them to stand and tapered for others. The pilot and co-pilot wear a half vest providing protection only in front, since their backs are protected by armor plate fitted to the aircraft. A full vest weighs 16 pounds, a full apron 6½ pounds.

Col. M. C. Grow, surgeon of the United States Eighth Air Force, is responsible for the development of the idea. After months of operations he found that most of the wounded airmen were injured by low velocity missiles. Whereas armor which would stop everything was not practical, he believed that these low velocity missiles could be stopped by light armor. He went to the headquarters of the London police and was recommended a manufacturer of bullet proof vests. He took a designer from this plant and got him to watch an experienced combat crew in a grounded flying fortress going through the motions of firing the guns and doing their respective jobs. In addition to affording protection, the armor had to meet three

specifications. It must not hamper operational efficiency, it must not be so heavy as to produce fatigue and it must be shed quickly in an emergency. The London firm, which has specialized in sword making since 1772, produced an experimental model that met all these specifications. Colonel Grow had the vest tested with a 0.45 caliber army pistol at 30 feet. The bullet did not penetrate even at the joints where the metal plates overlap. Colonel Grow is now working on a close fitting helmet having the same flexibility that the unjoined steel plates give the vest.

Diphtheria as a War Danger

The danger of invasion by diphtheria is mentioned in a report by the Medical Research Council. The history of diphtheria epidemics suggests that our epidemiologic invasion lines run from the south of Europe, and this has to be borne in mind now that North Africa has become a theater of war. Advocating immunization on the widest scale, the report says that, although its value was known almost a generation ago, diphtheria has continued to be a major cause of mortality, and there is reason to think that in certain sections of the population the danger has increased. Though there has been a decline of 60 per cent during the past forty years, it is short of what has been accomplished elsewhere. The mortality is declining more quickly at preschool than at school age. This is explained by the fact that in overcrowded areas the families have become smaller and less crowded owing to improved housing. Hence the children are less exposed to infection in their preschool life but more contract the disease in school life. It has been estimated that 2 to 5 per cent of London school children are carriers of virulent diphtheria organisms. Why they remain healthy in other respects has not been explained, or why some clinical cases always remain in the carrier state.

Postwar Blood Transfusion

The British Red Cross Society announces in its annual report its willingness to organize a national blood transfusion service to come into operation with the end of the war. A much greater demand for blood donors than ever known before in times of peace is expected to arise immediately after the war. The present emergency blood supply depots may cease to function and their places will have to be taken by local services. Conditions as uniform as possible will be necessary, so that donors may be able, when removing to another district, to transfer to the new service with the certainty of finding the same standard of skill, consideration and protection. For this a national organization such as exists in most other countries is necessary. Conferences have been held, at one of which representatives of the fighting services attended, to prepare the basis for this national service.

At the request of the Ministry of Home Security both men's and women's detachments of the Red Cross have been given instruction at military airdromes in the technicalities of giving first aid to crews of crashed aircraft. They have been taught the method of approaching the aircraft, how to get at trapped members of the crew, methods of releasing belts and harnesses, the types of rescue tools carried in the aircraft, where to look for the tools and how to use them, and fire risks. Already lives have been saved by this rescue service.

Mr. R. Watson-Jones Transfers to London

Mr. R. Watson-Jones, orthopedic surgeon, of Liverpool, is to transfer to London. He has accepted the invitation of the London Hospital to join the honorary staff as director of the new Accident and Orthopedic Department. The transfer to London of provincial surgeons has always been a very rare event.

BUENOS AIRES

(From Our Regular Correspondent)

April 16, 1943

Hypertensive Substance

Drs L F Leloir, J M Muñoz, A C Triguero, E Braun Menéndez and C Pasciolo all of Buenos Aires, recently reported the results of investigations which were carried on with the aim of ascertaining the origin and mechanism of formation of hypertensive substances. Hypertensinogen is a globulin of the blood plasma which is obtained by a process of fractional precipitation in plasma by means of ammonium sulfate. These investigators do not accept Page and Helmer's theory concerning the presence of hypertensinogen in blood globules. Renin has an effect on hypertensinogen with consequent formation of hypertensin. The seat of origin and mechanism of destruction of hypertensinogen were unknown. Page and his collaborators believe that both the formation and the destruction of the substance occur in the liver and that the mechanism of destruction is similar to that of dextrose. Leloir confirms Page's statement but objects to Page's technique as the latter's studies were made on hepatectomized animals with kidneys which constitutes a cause of error. Leloir and his collaborators removed several organs which permitted them to identify with certainty the place of formation of the substance. They employed Muñoz's technique for determining the substance in citrated and centrifuged blood. Leloir's method was used for measuring the amount of renin. The authors found that the amount of hypertensinogen does not change in animals with abdominal evisceration. In animals in which hypertensinogen disappeared from the plasma because of an injection of renin the removal of the abdominal viscera with the exception of the liver results in reappearance of hypertensinogen in the plasma in normal quantities. Hypertensinogen is rapidly resynthesized if a plasmagenesis is performed in nephrectomized dogs but resynthesis does not occur after evisceration. These investigators conclude that hypertensinogen is formed and synthesized in the liver. The substance used by the liver in synthesizing hypertensinogen is not known. When the amount of hypertensinogen in the plasma is highly concentrated the liver stops production of the substance. Renin changes hypertensinogen into hypertensin which is eliminated through the kidney.

Congenital Tuberculosis

Dr Mario Waissmann made observations on 737 tuberculous women who were delivered in the Maternity Department of the Hospital Torno of Buenos Aires. His observations extended from 1934 to 1942. In the whole group of infants of 737 tuberculous mothers 11 died from congenital tuberculosis (1.46 per cent). Probably the figures would have been higher if necropsy could have been performed systematically. The majority of children from tuberculous mothers grow normally. Congenital tuberculosis develops only when tuberculous lesions are present in the placenta. This occurrence is more frequent in patients with grave forms of tuberculosis than in patients with mild forms of the disease. Transplacental tuberculosis is not necessarily fatal. Dr Waissmann carried on careful observations on the embryofetal circulation. After the third month of intra-uterine life the volume of blood carried to the heart and lungs is considerably increased. That is why pulmonary tuberculosis is the predominant form of congenital tuberculosis. On the basis of the known facts concerning embryofetal circulation, the existence of congenital pulmonary tuberculosis cannot be denied. The differential diagnosis between congenital and acquired tuberculosis in infants is done by ascertaining whether or not the infant was separated from the mother immediately after birth and removed to a safe environment. The only possibility of protecting the infant against tuberculosis is separating it from a tuberculous environment.

Kenny Treatment of Poliomyelitis

An epidemic of poliomyelitis has existed for several months in Buenos Aires. A committee consisting of Dr Ruthertford L. John, associate professor of orthopedic surgery of the University of Pennsylvania School of Medicine, and two nurses recently arrived in Buenos Aires for the purpose of teaching the application of the Kenny method. Various committees of South American physicians, surgeons and orthopedists and three poliomyelitis committees in Argentina organized to carry on the work. Practical sessions for teaching the application of the method were held in the Hospital de Niños and the Muñoz Hospital of Buenos Aires. Dr John has also given courses on the subject. Large numbers of South American physicians, surgeons and orthopedists were present. Dr John was especially invited to give lectures to the Argentine societies of pediatrics and orthopedic surgery.

Society Reunion

The first annual meeting of the Society of Rheumatology of Rio de la Plata was held in Montevideo, Dec 18 and 19, 1942, under the auspices of the Liga Uruguaya contra el Reumatismo. There was a large attendance of Argentine, Brazilian, Paraguayan and Uruguayan physicians. Resolutions were adopted: (1) to consider rheumatic diseases a problem of public health for the government; (2) to ask the government for the organization and establishment of proper centers and hospitals for the prevention and therapy of heart disease and also for hospitalization of convalescents; and (3) to give unanimous support to the organization and establishment of the Pan American League Against Rheumatism. A South American committee, the members of which are in charge of preparing a well coordinated terminology of rheumatic diseases was appointed. It was made up of Drs Rafael Bullrich, Pedro Cossio and Aníbal Ruiz Moreno of Argentina, Genival Soares Londres of Brazil and Fernando Herrera Ramos and Bolívar Delgado Correa of Uruguay. The second annual meeting of the Society of Rheumatology of Rio de la Plata will be held in July 1944.

Inexpandable Lung

Drs Mariano R. Castex and Egidio S. Mazzei of the First Medical Clinic of the Faculty of Medicine of Buenos Aires confirmed by clinical observations the fact that artificial collapse therapy of pulmonary tuberculosis may be the cause of inexpandability of the lung with consequent chronic pneumothorax, pleurisy and some other diseases. Inexpandability may also follow pleurolysis and operation for empyema. In cases of inexpandability of the lung of intrinsic origin, respiration in mechanical chambers may produce an acceptable degree of reexpansion and prevent the need of a thoracoplasty. In cases of retention of secretions in the bronchi the therapy by the bronchial route is useful and may make operation unnecessary.

Brief Items

The government of Argentina made an allowance of 5,981,960 Argentine pesos for the 1943 budget of some university clinics and of some other scientific institutions. The budget of the Faculty of Medicine of Buenos Aires is for 3,713,340 pesos. That of a group of other scientific institutions is for a total amount of 2,268,620 pesos.

Dr Nicolás Romano of Buenos Aires was recently appointed to the chair of clinical medicine of the Faculty of Medicine of Buenos Aires which was made vacant through the resignation of Dr Rafael Bullrich. Dr Romano has been professor of the second chair of clinical medicine of the Faculty of Medicine of the University of La Plata since 1935. He is the president of the Argentine Medical Association and the author of various important books on clinical medicine, respiratory diseases and other subjects.

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission
and Promoters of Various Products

The following items are abstracts of stipulations in which promoters of "patent medicines," medical devices and cosmetics have cooperated with the Federal Trade Commission to the extent of agreeing to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Amor Skin—That this product or any other preparation of substantially the same composition, whether sold under the same or a different name, will feed or nourish the skin or that its use will improve the structure or tissue of the skin or have any effect on the contour of the elbow, were misrepresentations which the Amor Skin Corporation of New York agreed to drop from their advertising in a stipulation that they signed in January 1943 with the Federal Trade Commission.

Beecham's Laxative Pills—Beechams Pills, Inc., Bloomfield, N. J., and Atherton and Currier, Inc., New York advertising agency, stipulated with the Federal Trade Commission in October 1942 that they would discontinue any advertisement which failed to reveal that these pills should not be used when abdominal pain, nausea, stomach sickness or other symptoms of appendicitis are present provided, however, that such advertisements need only contain the statement, "Caution Use only as directed," if the directions for use, wherever they appear on the label or in the labeling, contain a warning to the same effect.

Breosan Products—These are put out by a Paul Sturzenegger, trading as Breosan Laboratories, Long Island City, N. Y. In January 1943 Sturzenegger entered into a stipulation with the Federal Trade Commission in which he agreed to discontinue the following representations in his advertising: that the "Breosan Treatment" or "Breosan Suppositories" have any value in the treatment of hemorrhoids other than as an emollient and palliative, that "Breosan Solution" is prophylactic or antiseptic, will cause wounds to heal without scars or promote the growth of new tissue, is not a drug or has any beneficial effect in the treatment of wounds, abrasions, blood poisoning, boils or other ailments enumerated in his advertisements, or that either "Breosan Ointment" or "Breosan Lanolin" has any beneficial effect in the treatment of wounds of many kinds, burns, chapped hands or similar disorders.

Coates Tablets—These are alleged food preparations comprising "C8 Vegetable Tablets," "B5 Vegetable and Dulce Tablets," "B6 Tablets," "B3 Vegetable Tablets," "BA Vegetable Tablets," "C16 Vegetable Tablets" and "C11 Tablets." They are put out by a Bertha B. Johnson, trading as Coates Concentrates, Chicago. In January 1943 the Federal Trade Commission announced that it had accepted a stipulation from her in which she agreed to cease representing that these products will correct, prevent or overcome mineral or vitamin deficiencies, provide more minerals and vitamins than one would obtain from assimilating two pounds of fresh vegetables that her nostrums will provide an alkaline balance or aid tissue building or rich in vitamins or minerals that they will provide a substantial amount of silicon for the enamel of bones and teeth that they will preserve youthfulness, relieve pain, balance weight, or heal, that they are a brain or nerve food or are important to the liver, kidneys, spleen or pancreas or provide laxative effects, that the C11 Tablets will relieve symptoms of high blood pressure or that the B6 Tablets are a tonic or will overcome "tired feeling." Bertha B. Johnson further agreed to discontinue any advertising which failed to reveal that her "C14 Tablets" and "Coates Concentrates C12 Laxative Tonic Tablets" should not be used when stomachache, nausea, vomiting or other symptoms of appendicitis are present, provided, however, that such advertisement need only contain the statement, "Caution Use only as directed" if and when the directions for use in the labeling contain a warning to the same effect. The respondent further stipulated that she would discontinue representing that neither of these preparations contains drugs.

"Dr. Coleman" Mattresses—These and some studio couches bearing the same brand name, have been put out by the Gerson Bedding Company, Lowell, Mass. This concern, in January 1943, stipulated with the Federal Trade Commission that it would cease using the word "doctor" or the abbreviation "Dr." either alone or in connection with the name for any of its products so as to convey the impression that they have been made in accordance with the design of, or under the supervision of, a medical practitioner or that such products contain special scientific or health measures which are the result of medical determination or the services of a doctor of medicine, provided, however, that if the name "Dr. Coleman" is used in connection with the marking, branding, or labeling of mattresses made in accordance with the directions of, or under the supervision of, the named person, it shall be immediately accompanied by some other

word or words such as "Osteopath," "Osteopathic Physician" or "Doctor of Osteopathy" so as to indicate clearly that the named person is other than a medical practitioner. The concern further agreed to cease using the word "health" either alone or in connection with any other words, as descriptive of mattresses, so as to convey the belief that the products have therapeutic qualities which would be of value in connection with the cure or prevention of diseases or that they are of such nature as would guarantee or assure health to or the maintenance of health by their users.

Halex—In January 1943 one A. P. Klase, trading as Halex Company, Sappington, Mo., stipulated with the Federal Trade Commission that he would discontinue representing, among other things, that this product is of value for hay fever, asthma, catarrh, migraine, sinusitis, toothache, cold sores, drowsiness, fainting spells, lung colds, influenza or sore throat.

La Vida Mineral Water and La Vida Blue Label Water—These are put out by La Vida Bottling Company, Inc., Placentia, Calif. In January 1943 Paul G. Hausman, president, William N. Miller, vice president, and Alfred D. Mitchell, secretary, of this concern signed a stipulation with the Federal Trade Commission, agreeing to discontinue the following misrepresentations in their advertising: that the products named have any therapeutic effect other than that afforded by their sodium bicarbonate content or that they are competent remedies or effective treatments for kidney and gallstones, diabetes, neuritis, rheumatism, stomach ailments, liver and bladder troubles caused by excess acid, or the condition resulting from excessive indulgence in alcohol, or that the products attack any ailment at its very foundation or add any minerals to the system in adequate quantity. They also agreed to stop representing that the usual or ordinary diet is "highly acid forming", that cooking destroys the alkaline content of foods, or that the respondents' products can be depended on to restore alkaline balance.

Sorature—Under this brand name are sold certain surgical supplies, including wound clips, by a Belle Propper and a Seymour Schumann, trading as Dr. Propper Manufacturing Company, New York. According to a release issued by the Federal Trade Commission in February 1943, these two persons signed a stipulation with the Commission in which they agreed to discontinue the word "Manufacturing" or the abbreviation "Mfg." or any other word or term of like meaning as part of their trade name. Further, they agreed not to use such word or term in any manner implying that they actually own, operate or directly control the factory in which the products which they sell are manufactured. The stipulation further provided that these persons would no longer use the abbreviation "Dr." or any other word or term of like meaning as part of their trade name, and that they would cease using such abbreviation in a manner which might tend to convey the belief that the wound clips were designed by or manufactured under the supervision of a physician.

Shampo Kolor—This was described by the Federal Trade Commission as a coal tar hair dye sold by Valligny Products Inc., New York. In December 1942 the Commission reported that it had accepted a stipulation from the Valligny concern in which the latter agreed to cease disseminating any advertisements which did not conspicuously carry the warning "Caution This product contains ingredients which may cause skin irritation on certain individuals and a preliminary test according to accompanying directions should first be made. This product must not be used for dyeing the eyelashes or eyebrows, to do so may cause blindness." The stipulation provided, however, that such advertisement need contain only the statement, "Caution Use only as directed on the label" if such label bears the first described caution conspicuously and the accompanying labeling bears adequate directions for such preliminary testing before each application. Incidentally, in April 1940 the Commission had definitely ordered the Valligny concern to discontinue certain representations in the sale of "Shampo Kolor." Among these were that the product is capable of coloring the roots of the hair or affecting the color of new growth hair, that the use of this product restores the color to the hair, that it is made in France and is "uniquely different or entirely revolutionary in methods or results."

Vitamalt and Natura Calcium Compound and Vitameal—These are sold by one Frank E. Carter, trading as Three Palms Pharmacy, Los Angeles. In January 1943 the Federal Trade Commission reported that this person had signed a stipulation with the Commission in which he agreed to desist from representing that either of these preparations has any reducing action, or that any weight loss resulting from following the directions for their use is other than such as would naturally result from a starvation diet or abstinence from food that these nostrums or the diet prescribed therewith can be depended on to bring about weight reduction of ten pounds in five days or that such diet will effectuate any weight reduction in excess of that resulting therefrom that the diet prescribed with "Vitameal" will not cause or result in weakness or hunger, that the use of either product with rich food has any building tendency or any practical significance from the standpoint of caloric intake that either will give new life or freshness to the skin or free it from pimples or blotches, keep the glands and nerves functioning or nourished, have any beneficial effect on the body metabolism, vitalize the system, cause the pains of rheumatism, arthritis or lumbago to disappear or provide a competent treatment for nervousness, rheumatism, stomach trouble or constipation. Carter further agreed to cease representing that taking either product as directed will cause a weight reduction safely without lowering resistance to disease or otherwise endangering the health, that Vitameal is a tonic or that the "Vitameal Way" of allegedly reducing weight does not consist of fasting, that Vitameal supplies all the needed vitamins or that the specific function of vitamins is to feed the various glands of the body, that the administration of vitamins in excess of ordinary requirements will result in health, superior physical condition or strength, or increased resistance.

Correspondence

TUBEROUS SCLEROSIS AND TOXOPLASMIC ENCEPHALOMYELITIS

To the Editor—I agree with the opinion expressed by Drs Merritt and Aring in their communication to THE JOURNAL, July 24, page 892, with regard to the diagnosis on the father and son described under the heading of 'Familial Tuberos Sclerosis (Epiloia) Without Adenoma Sebaceum' in the issue of June 12. The authors apparently have not only misinterpreted the significance of the ocular findings in case 1 but did not recognize the negative diagnostic importance of their absence in case 2.

The presence of ocular lesions with special reference to retinal and to chorioretinal morbid processes in tuberos sclerosis and in toxoplasmic encephalomyelitis (particularly the infantile, or congenital, form of the latter) respectively, in essentially all cases is high on the list of the established criteria for the clinical diagnosis of these disease entities (Koch, F. L. P., and Walsh, M. V. Syndrome of Tuberos Sclerosis *Arch Ophth* 21:465 [March] 1939; Koch, F. L. P., Wolf, Abner Cowen, David, and Paige, Beryl H. Toxoplasmic Encephalomyelitis, *ibid* 29:1 [Jan.] 1943).

Typical retinal tumors not unlike the surface of an unripe mulberry in appearance invariably occur in tuberos sclerosis while in congenital or infantile toxoplasmic encephalomyelitis there are seen essentially without exception bilateral, more or less atrophic as well as pigmented central (or macular) as well as more peripheral, fairly extensive patches of chorioretinitis. It is most probable that the onset of these patches in their acute phases occurs prenatally or in infancy or in both but not in childhood or later. There is no reason however to suppose that they do not continue to exist throughout the life of the afflicted patient or that they do not remain diagnostically recognizable. The latter is equally true with regard to the characteristic tumors of the optic disk and of the retina in tuberos sclerosis, an entity in which chorioretinitis has not yet been observed as such probably for the very good reason that the tumors are not inflammatory or micro-organismic in origin.

It had been thought that these tumors manifested themselves primarily as proliferations of embryonal cell rests during the complex changes attendant on puberty and adolescence until Gruner reported his case (Tuberos Sclerosis *ibid* 27:1234 [June] 1942). In the discussion following the presentation of that case I raised the question of differential diagnosis with respect to toxoplasmic encephalomyelitis, which at that time was under intensive investigation in the Columbia-Presbyterian Medical Center especially with regard to the diagnostic significance of the ocular lesions. It became obvious during the study not only that it was necessary to conduct entirely objective examinations of the eyes and of the eyegrounds but also that it was imperative to avoid the diagnostic pitfalls inherent in the tendency to relegate certain apparently associated diseases to a single clinical wastebasket merely to serve the false purposes of categorical simplification.

I refer particularly to the so-called phakomatoses of van der Hoeve (Eye Symptoms in Phakomatoses *Tr Ophth Soc U K* 52:380, 1932)—the 'related' neurocutaneous syndromes of tuberos sclerosis (diffuse neurospongiblastosis), von Recklinghausen's neurofibromatosis, von Hippel-Lindau's retinal and cerebral angiomas and Sturge-Weber's angiomas of the cerebrum—none of which have a common clinicopathologic background except for the hypothesis that their occurrence might possibly support Cohnheim's embryonal cell rest theory. There is no valid reason for the clinical misrecognition of any one of these syndromes nor should there be interconfusion with toxoplasmic encephalomyelitis. The presence of the ocular lesions or their

absence, is pathognomonic in the main and, together with their correlation with the already full reported confirmatory findings inclusive of the usually informative history, should lead to accurate diagnoses in all instances.

"PSYCHOANALYSIS AND THE SCIENTIFIC METHOD"

To the Editor—Will you permit me to comment on the important editorial 'Psychoanalysis and the Scientific Method' (THE JOURNAL, July 17). Taken as a whole, the article is correct. The obscure sentence that you quote from the psychoanalytic article is not only significant but typical. Any physician who will go to a medical library and read through four or five issues of psychoanalytic journals will find the same type of sentence—or even worse ones—over and over again. The conclusion is inescapable that to this involved and obscure language there must correspond an involved and obscure type of thinking. But it must be pointed out that this criticism does not apply to Freud himself. In expression in thinking and in style he was always clear and his greatest contribution is that he drew human problems into the range of scientific inquiry and gave tremendous impetus to the humanizing of psychiatry. It is a strange paradox of medical history that so many of his present day followers have become so unclear and needlessly esoteric.

The Association for the Advancement of Psychotherapy is making a serious attempt to develop Freud's ideas and methods along lines that appear to us more clinically practical and more scientific. One of our aims is to abbreviate the long procedure of psychoanalysis and to bring it into closer relationship with other branches of medicine and psychotherapy.

Constructive abbreviation of the long and expensive psychoanalytic procedures does not consist merely in shortening them, they must be changed as well. Such abbreviation is of great importance for many patients who otherwise cannot get the benefits of psychoanalysis at all and it also remedies to a large extent the two difficulties mentioned in your editorial, namely the treatment of members of the medical profession and the question of the training of psychoanalysts.

May I draw your attention to some books—Franks' *Morbid Fears and Compulsions*, Guthrie's *Language of the Dream* and Wertham's *Dark Legend*—which demonstrate that the most complex problems and facts of psychoanalysis can be simply and clearly expressed, so that any physician can understand and use them.

PREVENTION OF DYSENTERY BY THE USE OF SULFAGUANIDINE

To the Editor—The account by Scott of the successful prophylactic use of sulfaguanidine against bacillary dysentery interested me because of a somewhat similar personal group experience.

On an earlier visit to Mexico all in our party suffered the discomfort of what appeared to be a very prevalent tourist affliction—dysentery. On a second visit in March 1942 the three of us took a prophylactic bedtime dose of only 0.5 Gm. of sulfaguanidine. (At this hour the drug would have the least dilution with bowel content and have the longest stay in the intestinal tract.) Despite what seemed a 90 per cent incidence of dysentery (some severe cases) in our fellow travelers, none of us had the slightest gastrointestinal symptoms.

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts Suicide While Mentally Depressed Because of Effects of Industrial Injuries—During the course of his employment Barber fell astride a hopper, rupturing his urethra and injuring his bladder. Pain in the back and pelvic region, frequency of urination and sexual impotence developed. He became moody and despondent and about a year after the industrial accident committed suicide by slashing his wrists. His widow sought compensation under the workmen's compensation act of Wisconsin, alleging that the pain and loss of sexual powers resulting from the industrial accident produced a mental depression and caused the workman to commit suicide. The industrial commission of Wisconsin found that because of his physical condition, which was due to the industrial accident, the workman developed a psychosis, causing him to become devoid of normal judgment, that in all probability he would not have committed suicide had it not been for the results of the industrial accident but that he had rational knowledge of the consequences of his act and acted with conscious volition to produce his own death, that the suicide did not result from insanity of such violence as to cause him to produce death in a delirium or frenzy, nor while suffering severe pain, and that the workman's act in committing suicide was an intervening cause for death and that therefore suicide and death did not proximately result because of the industrial injury. Compensation was accordingly denied the widow. The circuit court, Dane county, in effect, affirmed the action of the commission and the widow appealed to the Supreme Court of Wisconsin.

The findings of the industrial commission, said the Supreme Court, indicate that the industrial injury to Barber produced certain physical disabilities, that the pain and humiliation involved in these disabilities created for him what was an intolerable condition, and that he became profoundly depressed. With full knowledge of what he was doing he chose deliberately to end his life as an escape from these intolerable conditions. His morbid mental condition had not, however, progressed to the state of insane frenzy. He still had moderately intelligent mental power, rational knowledge of the consequences of his act, and the capacity for conscious volition. On these facts, the commission and the trial court correctly denied compensation to the widow for two reasons. First, section 102.03(1), Stats. (a section of the workmen's compensation act), excludes compensation for intentionally self-inflicted injuries. It is evident that death by suicide constitutes an intentionally self-inflicted injury, and where the insanity of the person so ending his life has not progressed to the stage of destroying capacity to entertain an intention, the statute plainly excludes compensation for the injury. Findings by the commission to the effect that Barber did not act on uncontrollable impulse or in a delirium of frenzy, but with conscious volition and in the exercise of a moderately intelligent mental power, with knowledge of the purpose and effect of his act, seem quite clearly to preclude recovery because of the exclusion of the section under discussion. Secondly, compensation must be denied the widow because the voluntary, wilful act of suicide resulting from a moderately intelligent power of choice is an independent intervening cause that precludes compensation. *Daniels v New York, etc Railroad*, 183 Mass 393, 67 N E 424. The physical injury sustained by Barber was not permanent in a physical sense. There was no physical injury of any sort to the brain itself. What happened was that Barber was unable to tolerate the pain, inconvenience and humiliation caused by his physical condition and deliberately chose to end his life. It was a morbid choice but was the deliberate choice of a person of moderately intelligent mental powers, with rational knowledge of the consequences, and the act itself was done with conscious volition.

The element of insane frenzy or ungovernable lunacy was wholly absent. The judgment adverse to the widow was accordingly affirmed.

However, in a strong dissent filed by Fowler, Justice, it was argued that the death was the direct "end result" of the injuries sustained in the accident. The condition caused by the accident, this justice said, caused the death. It is of no consequence that the industrial commission found that Barber was conscious that the cutting of his wrists would result in death or that the wounds were not inflicted in a delirium or frenzy without conscious volition. The effect of the bare facts of the case cannot be obviated whether Barber was sane or insane in a medical or psychologic sense or by the commission or the court adopting the view of one or another expert. Nor can such effect be obviated by calling the intervening act an intervening cause when it is not such. The slashing of the wrists was an intervening act but not an intervening cause. An intervening cause is one occurring entirely independent of a prior cause. When a first cause produces a second cause that produces a result, the first cause is a cause of that result. *Kramer v Chicago, M St P & P R Co*, 226 Wis 118, 276 N W 113, *Mokey v Lake Superior T & T Co*, 125 Wis 148, 103 N W 271. There is then a direct as distinguished from a broken sequence, and the first cause is a responsible and proximate cause of the result. This seems so plain as not to be set aside by any species of fine spun reasoning. Barber's act in slashing his wrists is no more an intervening cause of his death than is following the advice of a physician who is treating a plaintiff for injuries inflicted by the defendant, when so doing results in a condition to alleviate which the patient must take especial treatment not necessary or appropriate to treatment of his original injury, in which case the expense, loss and suffering caused by the especial treatment proximately result in the defendant's act, such as was held in *Sumner v Kimey*, Texas Civ App, 136 S W 1192. Under the bare facts of this case, in this judge's opinion, the original injuries by direct sequence of causation resulted in death, and liability under the workmen's compensation act follows whenever this sequence appears.

However, because of the opinion of the majority of the court, judgment against the widow was affirmed. *Barber v Burrell Engineering Co*, 6 N W (2d) 199 (Wis, 1942).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1953 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 15 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Persistence of Poliomyelitis Virus in Flies. F. B. Bang and R. W. Glaser—p. 320
Further Studies of 3T Strain of *Plasmodium Cathemerium* in White Pekin Ducks. F. Wolfson—p. 325

Subcutaneous Vaccination with Influenza Virus. Francis and his co-workers show that the tendency has developed to consider that procedures which increase the level of antibodies enhance resistance in a parallel manner. In the acceptance of such conclusions little consideration has been given to the pathogenesis of the disease or to an explanation of the manner in which circulating antibodies can influence the resistance of the superficial respiratory epithelium which the virus of influenza initially and selectively attacks. The evidence presented by the authors shows that when subcutaneous vaccination of human subjects with active or inactive influenza virus induces a significant increase in the titer of neutralizing antibodies in the blood, the capacity of the nasal secretions to inactivate the virus is also enhanced. It is suggested that the influence of vaccination on the nasal secretions rather than on circulating antibodies as such, is the factor which determines the efficacy of vaccination in prevention of the natural disease.

Persistence of Poliomyelitis Virus in Flies. According to Bang and Glaser, increasing emphasis is placed on the intestinal route of infection by the virus of poliomyelitis. It is natural that attention should again be directed to the role of flies. The authors studied the infection of adults and larvae of the common housefly (*Musca domestica*), the green-bottle fly (*Lucilia lepida* [caesar]), the stable fly (*Musca stabulans*), the blowfly (*Calliphora erythrocephala*) and the flesh fly (*Sarcophaga hemorrhoidalis*). The experiments were not undertaken with the purpose of yielding definitive data on the question of fly transmission of human poliomyelitis but rather to furnish a biologic background for such a study. The different results obtained with the two viruses (Theiler's virus and the Lansing virus) suggest that more work on human viruses must be done. The results are in agreement with the work of Howard and Clark, who in 1912 found that *Musca domestica* fed on monkey cord infected with a human strain of poliomyelitis would retain the virus for at least forty-eight hours and that this virus might be recovered from the viscera of the fly. The consistently negative attempts to isolate virus from adults when the larvae are infected suggest that infection of larvae in nature is not important in the spread of the virus. The virus may

be recovered from the adult fly only when the adult itself is infected by feeding. Theiler's virus may be recovered from *Musca domestica* as long as twelve days after infection, but the mouse adapted human strain survived only two days in the housefly. The authors were unable to recover the mouse adapted Lansing virus from the four other species tested, while results with the mouse poliomyelitis in these species did not differ essentially from those obtained with *Musca domestica*.

Early Diagnosis of Cancer of Stomach. Held and Busch divide cases of cancer of the stomach into two groups: those in which the cancer develops in a healthy gastric mucosa and those in which the cancer develops on a previously diseased mucosa. Approximately 70 per cent of all cases belong to the first group. The slowly growing cancers that develop on a healthy gastric mucous membrane should be operated on even if a large palpable mass is present, because they do not exhibit a tendency to early metastasis. Lasting and good results may be expected. Without operative intervention the mortality is 100 per cent. It is difficult to retell the percentage of five year survivals or even cures in the aforementioned groups, but in the absence of metastases and with a successful operation the patient can go on for many years without recurrence. The medullary form of carcinoma of the stomach usually arises on a previously healthy mucous membrane, grows very rapidly and has a tendency to early metastasis. The group in which the cancerous lesion develops on a previously diseased mucous membrane comprises 30 per cent of all cases and gastric complaints were present for many years before cancer developed.

while in others the growth of the cancer is so slow that the lesion remains localized for several years. The precancerous symptoms vary and are usually bizarre and noncharacteristic and are therefore interpreted mostly as neurogenic. There are three separate groups of clinical entities on the soil of which the cancer develops: (1) gastritis, (2) polyps and (3) gastric ulcer. Gastrosocopy has materially increased the percentage of early diagnosis of cancer. Cancer which develops on a previously diseased mucous membrane, as in the case of gastritis, polyposis or gastric ulcer, has a tendency to grow much slower, is more benign and, when diagnosed early, offers a chance for prolongation of life and even permanent cure. Individuals with ulcer symptoms without ulcer signs should be looked on with greater suspicion and more watchfulness for early cancer than those in whom ulcer is clinically and roentgenologically demonstrable. A high degree of anemia and the size of the palpable mass should not deter one from operative intervention, provided preoperative and postoperative treatment are carried out with the greatest care.

Sulfathiazole Injury to Kidneys and Brain.—Luetscher and Blackman give detailed histories of 3 patients with severe sulfathiazole intoxication and of 2 patients with probable sulfonamide poisoning. All the patients developed an unusual increase in serum sodium and chloride concentration. When continuous observations were made, the electrolyte disturbance appeared while oliguria and nitrogen retention diminished. The excessive height of the serum electrolyte concentration probably contributed to the death of 2 patients. The renal lesions found in 2 cases suggest that the dissociation of salt and water excretion may be related to changes in certain specific portions of the tubule. There were thrombi in the interlobular veins in 2 cases. In 1 of these, thrombi in both interlobular arteries and veins were numerous and probably produced the renal lesions. In both cases the thrombosed veins were associated with ruptured tubules and the proliferation of tubular epithelium in the thrombi. Both patients developed moderate hypertension. Clinically there was evidence of cerebral damage. In the 2 patients who survived the uremia and hyperchloremia, signs of injury to the central nervous system persisted with slow and incomplete recovery. In the examined brains areas of edema and gliosis were found together with small hemorrhages in 1 case.

Ménière's Syndrome and Migraine.—In an earlier report Atkinson demonstrated that cases of Ménière's syndrome can be divided into two groups by means of an intradermal histamine test. There is a small group which is sensitive to histamine and which presents a primary vasodilator or allergic basis. This group can be satisfactorily treated by desensitization to histamine or by elimination of the specific antigen. In a second group, which constitutes the large majority, there is no sensitivity to histamine and the attacks are the result of a primary vasospasm. In this group relief can generally be obtained by administration of vasodilator drugs, of which the most satisfactory is nicotinic acid. In migraine also there is evidence of a dual etiology of the same nature as in Ménière's syndrome. Allergy as a cause of migraine attacks has been generally accepted as applying to at least a portion of the cases. On the other hand, Wolff and his collaborators have shown that migraine attacks can be the result of a primary vasospastic process. Thus the syndrome of Ménière and migraine are identical as far as the mechanism of their production is concerned. They differ in the location of the impact—in the one case it is on the labyrinth, in the other on the cerebral hemisphere. What determines location or laterality is not apparent. The two syndromes differ too in the frequency of occurrence of the two groups. Whereas in Ménière's syndrome the primary vasodilator group is a relatively small one compared with the vasoconstrictor, in the migraine syndrome the position, if not reversed, is at least more nearly equal. Allergy as a cause of migraine is common, as a cause of paroxysmal vertigo is uncommon. This fits in with the age groups in which the two syndromes arise—paroxysmal headache is a condition of youth, like the vasodilatation which produces it, paroxysmal vertigo a condition of middle life or later, like the vasoconstriction which is its usual cause. Nicotinic acid is used in the treatment of the vasoconstrictor group not because it is a part of the vitamin B complex but because it is a power-

ful capillary vasodilator. It is this basic vascular mechanism which presumably explains the satisfactory results reported with such divergent substances as thiamine hydrochloride and estrogens—both have a certain vasodilator action apart from their specific replacement function. The author directs attention to the frequent association of migraine and Ménière's syndrome. He encountered migraine in 22 of 108 cases of Ménière's syndrome. Migraine attacks have been known to merge into Ménière attacks. Treatment which has proved successful in relieving the vertigo of patients with Ménière's syndrome has also relieved the migraine headache in those cases in which it also has been present. Treatment of this syndrome, whether characterized in the main by vertigo or by headache, to be successful depends on accurate grouping of cases. No single method will achieve success in all cases, for there is more than one cause.

Lobectomy for Pulmonary Tuberculosis.—Churchill and Klopstock report lobectomies performed for pulmonary tuberculosis. All of the patients had positive sputum. A preoperative diagnosis of tuberculosis was made in every instance. Resection of upper lobes by individual ligation technique have been routinely practiced at the authors' hospital since 1936 and total 21 in number. In this paper they review 6 cases, 3 presented orthodox indications for resection of the lesion by lobectomy. Three others presented the usual indications for thoracoplasty, but lobectomy was performed instead. Primary healing took place in all instances. Lobectomy provides a more selective and immediate method of eradicating certain tuberculous lesions than does collapse therapy. It may be resorted to subsequent to artificial pneumothorax.

Prevention of Shock and Death by Pressure Dressing.—Fell and Hanselman anesthetized 10 dogs with pentobarbital sodium and maintained them under light anesthesia for ten to twelve hours. The right hind extremities were immersed to the upper third of the thigh in a mixture of solidified carbon dioxide and 95 per cent alcohol, at -55°C for twenty minutes. The entire portion was frozen within two minutes. Five of the dogs received no treatment and their legs were allowed to thaw out at room temperature. To the frozen hind legs of the other 5 dogs two to three layers of sheet wadding were applied and over this a plaster encasement. All 5 of the untreated dogs developed clinical shock, 4 of them dying within thirteen hours. All the treated dogs lived. The maximum increase in the hematocrit was only about half as great as in the untreated group. The thawing out of the encased legs was extremely slow, they were cold and moist for twelve hours or longer. The plaster encasement affords a firm even pressure.

splintage and allows for slow thawing. Four of the 5 treated dogs developed necrotic limbs. Two dogs had their necrotic amputated extremities amputated eight and eleven days after freezing and made uneventful recoveries. Another dog had his leg amputated forty-eight hours after freezing and likewise recovered. The authors think that pressure dressing could be applied to frozen compressed or burned parts. The time for such application is before the swelling sets in immediately after the limb has been released from the crushing load directly after the burn, and before any thawing of the frozen part has taken place.

Brucellosis—The chronic phase of brucellosis is often overlooked. Doctors practicing in rural districts or in towns where pasteurization of milk is not legally required should always consider this disease in diagnosing chronic illness. Urschel consider this disease in diagnosing chronic illness. Urschel tested 124 patients with suggestive histories for brucellosis by means of intradermal vaccine. Seventy of these, or 56.4 per cent, gave a positive skin reaction to the Brucella abortus and Brucella suis vaccine. Fifty-three or 42.8 per cent were considered to have clinically active brucellosis. Only 2 children were encountered with the condition. The average age of the patients was 41. Twenty-three per cent of the active cases gave a history of exposure to Bang's disease in cattle. All of these patients consumed raw milk. Forty-three per cent of the active cases gave a past history of febrile illness suggestive of brucella infection. Tiredness was the most common symptom. Other symptoms were headache, weight loss, weakness, nervousness, fever, constipation, bloating and chest pain. The number of positive agglutination reactions prior to treatment was low. The hematocrit reading showed a high average volume of packed red cells, otherwise the laboratory findings were not significant. Most of these patients were treated with subcutaneous or intradermal administration of vaccine or with a combination of the two. Of the treated patients 88.7 per cent improved while 11.3 per cent did not improve. There was little difference in the results of subcutaneous and intradermal vaccine therapy. The latter method has value when unexpected febrile responses occur from subcutaneous vaccine treatment. It remains to be proved whether the antibody response varies in the two methods.

Pulmonary Atelectasis—Bronchoscopic aspiration is the recognized treatment of postoperative pulmonary atelectasis, but the method is not readily available in many hospitals. The stir up regimen so widely advocated by Waters helps prevent atelectasis in the postoperative period. It consists of three

points: 1 The patient must radically change his position. 2 He must cough vigorously. 3 He must take several deep breaths. For the tracheobronchial toilet the anesthetist can introduce a soft rubber tube between the vocal cords and aspirate the tracheobronchial tree. The tracheobronchial toilet is useful when the patient is too weak or too depressed to cough out the pulmonary secretions, which will accumulate and prevent adequate oxygen exchange. This is seen after cerebral accidents or brain operations. Prompt drainage is of value, and repeated aspirations may be necessary.

Poliomyelitis Virus in Flies—During the summer and fall of 1941 Trask and Paul collected 19 samples of flies in epidemic areas both during and after epidemics of poliomyelitis. Of 8 samples collected for the most part during the latter part of a local epidemic but within ten days of the onset of a local case of poliomyelitis 4 yielded the virus, whereas of 8 samples collected more than ten days from the onset of the last local case none yielded the virus. In 4 instances there was a potential though not proved source of virus in the form of "exposed" human feces or recent origin within a few yards or few feet of the site where flies were collected. Collections of flies from three of these sites yielded the virus.

Persistence of Leptospira Antibodies—According to Packchamian and Tom, laboratory and clinical data are available to prove that patients suffering from Weil's disease produce specific antibodies against Leptospira icterohemorrhagiae and that the presence of such antibodies can be demonstrated in the circulating blood by serologic and immunologic tests. These antibodies may persist in the patient's blood for a long time after complete recovery, thus making possible a retrospective diagnosis. Eight persons who had recovered from Weil's disease from two to over twenty years still had agglutinins for type I Leptospira icterohemorrhagiae present in their circulating blood in significantly high titer. The average level of agglutinative titer during the active phase of the disease in 7 cases was 1:23,000. The minimal dilution in which agglutination occurred between two and twenty years after complete recovery was 1:100 while the maximal was over 1:30,000.

Staphylococcus Vaccine-Toxoid—Faust and Etris report that normal individuals receiving ten injections of staphylococcus vaccine-toxoid combined (Vator) showed a decided increase in both agglutinins and antitoxin. The average increase of agglutinins was fifty-seven fold and the average antitoxin increase tenfold when compared with the preinjection levels. Patients with known or suspected staphylococcal infec-

tion were on an average less responsive to antibody stimulation than the normal group, although after vaccination the serum of the patient with staphylococcal proctitis contained agglutinins and antitoxin in greater quantity than the average of the normal individuals. The use of staphylococcus vaccine-toxoid combined is a logical approach to the dual stimulation of antibacterial and antitoxic substances in the treatment of staphylococcal infections.

*Early Diagnosis of Poliomyelitis A V Stoesser—p 149

Early Diagnosis of Poliomyelitis—Recent interest in the Kenny treatment has made the early diagnosis of poliomyelitis important, since the treatment gives its best results when instituted as soon as muscle spasms appear. Stoesser presents a table of the early symptoms that were observed in a careful study of 259 acute cases admitted to the Minneapolis General Hospital during the past six years. The majority were children ranging in age from 1 to 14 years with the highest incidence appearing between 5 and 9 years. The average course of the disease was found to fall into the following phases: (1) fever, headache, nausea and vomiting, restlessness or irritability, (2) continued headache, stiff neck, pain on flexion of neck or spine, muscle pain especially on motion, (3) continued pain on flexion of neck and spine, drowsiness, muscle spasm and no motion. Spinal fluid examination may reveal little if the fluid is collected during the first phase, but during the second and third phases characteristic changes appear which may confirm the diagnosis. Some of the symptoms and signs may be more severe in 1 case than in another and lead to various types of onset—meningeal or cerebral, gastrointestinal and respiratory. Many diseases have been confused with poliomyelitis chiefly because some of their symptoms resemble the characteristic features of the various types of poliomyelitis. This is particularly true of acute upper respiratory infections. If no loss in muscle function occurs and a spinal fluid examination is normal, the diagnosis of poliomyelitis may be dropped. Meningitis may easily be confused with infantile paralysis. Occasionally a rather mild pharyngitis or tonsillitis will be followed by a symmetrical and bilateral loss of muscle function in the extremities. Although poliomyelitis is considered, this diagnosis is questioned because the motor impairment does not have the localized and asymmetrical distribution noted frequently in poliomyelitis. The onset of pneumococcal pneumonia in young children can simulate poliomyelitis. Encephalitis may be confused with the cerebral type of poliomyelitis when the latter progresses rapidly to the third phase and leads to extreme drowsiness. Careful inspection and palpation of the muscles, as recommended by Miss Kenny, reveal muscle spasm early in the course of the disease.

Control of Endemic and Epidemic Diarrhea—Control of diarrhea and dysentery is a major concern of armies in training and on combat duty. The high incidence of diarrhea in army troops on maneuvers during 1941 and the sporadic recurrence of outbreaks in 1942 have indicated the danger of similar outbreaks occurring under combat conditions. Efforts have been made to acquaint troops in training with proper control and sanitary methods. In order to establish proper preventive and control measures for diarrheal diseases all cases of diarrhea should be examined for the specific etiologic agent. The following laboratory procedures should be carried out in every case of diarrhea: (a) A swab culture of the rectal mucosa for pathogenic bacteria which is inoculated directly into inhibitive and differential mediums at the bedside of the patient. (b) Direct microscopic examination of the stool to determine the type of exudate, the cellular constituents and the other diagnostic criteria. (c) Direct microscopic examination of the stool for parasites. The Hardy swab method of culturing by use of the rubber catheter and swab and improved inhibitory mediums have simplified and made available a more accurate method of obtaining positive cultures. The predominating enteric pathogens isolated and identified in the Fourth Service Command Laboratory during the past year were found to be members of the genus *Shigella* (99 per cent). Sulfaguanidine and succinylsulfathiazole were used to treat 244 persons with acute bacillary dysentery or convalescing from it, and 182 of these were available for culture following treatment. All were negative by the swab method of culture on one to three follow-up cultures. Cultures from 60 control cases in which treatment was not given were found to be positive at a similar length of time following recovery from dysentery. The culturing of flies and the improved inhibitory mediums present a new application of bacteriologic methods in the determination of the transmitting agent in bacillary dysentery.

- Immunization Against Epidemic Influenza with Living Attenuated Virus F. M. Burnet — p. 385
Experimental Immunization of Volunteers Against Influenza Virus B Diana R. Bull and F. M. Burnet — p. 389
Intranasal Vaccination of Humans with Living Attenuated Influenza Virus Strains Jessica Mawson and C. Swan — p. 394

Immunization Against Epidemic Influenza with Living Virus—The method of immunization used by Burnet was to spray into each nostril egg fluid containing a high concentration of three living attenuated strains of influenza virus representing the main antigenic types. About 0.25 cc of virus was used for each subject. The proportion of persons showing a rise in antibody level is greatest among those having the lower initial antibody levels. Of the 91 subjects whose serum was fully tested, 46 showed a rise regarded as significant against one or more components of the vaccine. These results are considerably inferior to those obtained by American workers with subcutaneous inoculations, but the intranasal vaccine can be expected to take only in subjects susceptible to influenza virus infection. In the pandemic of 1918 about 70 per cent of persons escaped clinical infection. Even with an ideal vaccine of this type, one would not expect more than 30 to 50 per cent of subjects to show a definite rise in antibody level against any one type. In one unit of about 7000 men it was possible to obtain information as to the effect of immunization on the incidence of respiratory tract infection during a proved influenza epidemic. Immunization was being carried on in this unit during the period of influenza prevalence, and only two weeks were available in which (a) the immunized group had been inoculated more than one week previously and (b) the influenza epidemic was still current. During these two weeks 44 per cent of the immunized reported sick with some form of upper respiratory tract infection, as against 663 per cent of those not immunized. This apparent 50 per cent advantage of the immunized must be treated with reserve. There was at most only a minor benefit in this epidemic. The intranasal method has disadvantages and potential dangers. The possibility that the immunizing infection will exacerbate an infection in the nasal sinuses must be considered.

Immunization Against Influenza Virus B—Bull and Burnet have consistently found that results with influenza virus B are more regular than those obtained with type A strains. The level of circulating antibody (Hirst's method) is a fairly accurate index of susceptibility to experimental infection with living attenuated influenza virus B. The authors tested some modifications in the method of administering the virus and determined whether a primary administration or virus produced resistance to a second administration some months later. A blood sample was taken from about 100 volunteers to select

those whose serum tested by Hirst's method had a low antibody level against influenza virus B. The virus was administered in the form of allantoic fluid from embryos inoculated with the thirty-ninth amniotic passage of influenza virus B. Twenty-three volunteers with a low level of influenza virus B antibody were inoculated intranasally with attenuated influenza virus B and after three to six months received a second similar inoculation. There are indications that the procedure may provide a substantial protection against natural influenza B by showing that a subsequent inoculation produces a much lower proportion of antibody responses and of virus reisolations than the first series. It indicates the complexity of the problems of influenza, however, when it is considered that the proportion of minor symptoms was greater after the second inoculation than after the first. Twenty-one members of the group showed a significant rise in antibody level after the first administration, only two members did so after the second. Some evidence has been obtained that allergic factors play a part in the production of symptoms.

Intranasal Vaccination with Living Influenza Virus—Mawson and Swan treated one hundred volunteers with a single dose of virus. The vaccine consisted of pooled allantoic fluids from chicken embryos infected with the W/S and Melbourne strains of influenza virus A and with the Lee strain of influenza virus B. Up to the time of writing (five months after vaccination) no epidemic of influenza had occurred in the community. The efficacy of the vaccine, therefore, has yet to be tested. The authors also investigated the effect of repeated vaccination on volunteers who showed no antibody response to the first spraying. They conclude that, as far as antibody increase is considered the administration of living, attenuated influenza virus strains by nasal spray appears to have no advantage over the subcutaneous injection. There is a possibility that the resultant mild infection of nasal tissues will lead to an increase in local resistance not obtained by subcutaneous injection. Although the average increase in antibody against each of the three strains in the vaccine was approximately twofold, the individual responses varied from no increase to a twenty-seven-fold increase. Unless all those subjects showing no increase in antibody were already immune, those people would be a source of danger in a community in which large scale vaccination was relied on in an epidemic. Repeated vaccination failed to raise the antibody levels in the majority of cases. It is probable that they fall in the 50 to 90 per cent of people who do not contract influenza even in pandemic periods and that conversely the people responding to the nasal vaccine will be just those who will prove susceptible to a respiratory infection like influenza.

Experimental Mumps in Monkeys Attempts to Propagate the Virus in Hen's Eggs—Swan and Mawson collected saliva from 36 patients usually within twenty-four hours of the onset of parotitis. They inoculated the saliva into monkeys but only the last 3 or 4 experiments were successful. All 3 positive results were obtained from a specimen of saliva which comprised the pooled saliva collected from 4 patients within four to twelve hours of the onset of parotitis. The incubation period in these animals was ten, thirteen and sixteen days respectively. By injecting suspensions of the excised parotid glands of the animals thus affected into further monkeys it was possible to transmit the disease in three passages. The incubation period in the passage animals was five or six days. By the use of specimens of the cerebrospinal fluid of 4 patients suffering from mumps meningoencephalitis six attempts were made to isolate the virus. Positive results were obtained from only 1 of the 4 patients. In this case again passage succeeded in several monkeys. Two of eight attempts to cultivate the virus of mumps in developing hen's eggs gave suggestive but not necessarily positive results. Rabbits, mice, guinea pigs, and dogs remained well when inoculated with mumps virus by various routes.

Keratoplasty in Serpiginous and Other Ulcers—Tschet-schik-Kumina employed penetrating keratoplasty in the treatment of 15 patients with serpiginous ulcer of the cornea (mostly pneumococcal). The results were satisfactory. Pain and inflammation ceased and infiltration and opacity quickly subsided. In three fourths of the severe cases the eye was saved and in half of these visual acuity was satisfactory. Opacity of the transplant and formation of anterior synechia, eventually with increased pressure, were complications. The author is of the opinion that if the operation was extended to less severe cases the results would be even better. The nonpenetrating lamellar keratoplasty is inadequate.

Cerebral and Spinal Hydatidosis—Ley and Pons Tordera observed 3 cases of cerebral hydatidosis and 1 of spinal involvement among two groups of 200 intracranial tumors and 30 extramedullary spinal tumors. The patients in the first group were 2 women and a boy of 11 years. The clinical and neurologic symptoms were those of a benign intracranial tumor. Acute focal symptoms were present in all. The cerebrospinal fluid was normal. The operation consisted in a craniectomy, extirpation of the cyst and the membranes and irrigation of the operative field with a weak formaldehyde solution. The cysts proved to be primary and solitary in all of the cases. They were located in the posterior cerebral fossa in 2 cases and in the frontoparietal lobe in 1 case. The Weinberg and Cassoni tests performed after the operation gave a negative result in 2 cases and a slightly positive in 1. Eosinophilia was not observed. The cyst recurred in 2 cases. Extirpation of the recurrent cyst has been successful thus far four years and one year respectively after the operation. The patient with spinal hydatidosis showed symptoms and x-ray signs of medullary compression in the dorsal region. A hydatid cyst was found during the operation. It was successfully removed.

Diphtheria Immunity—Farago says that immunization against diphtheria has been obligatory in Hungary since January 1938. It is induced with a toxoid precipitate during the second and seventh years of life. He investigated the question whether immunization with 1 cc of precipitate during the second year of life conferred adequate protection until the seventh year. The Schick test was performed on 23,393 immunized children. On the basis of these studies and on epidemiologic observations Farago concluded that immunization with toxoid precipitate has proved its value. The natural antigen stimulus, the latent infection, plays its part. A single immunization is adequate as long as the present epidemiologic conditions prevail. Presumably, as the immunity increases, the latent infection will decrease in the course of years. If later the basic immunity of children should decrease, the adequacy of a single immunization may again have to be tested.

Immune Serums in Bacteriotoxic Inflammations—Saker found that intrathecal injection of cerebrospinal fluid from purulent cases of meningitis produces a severe inflammation of the arachnoid. Normal cerebrospinal fluid from sterile cases of meningitis does not cause any meningeal inflammation. He concludes that the infectious inflammation is caused quantitatively by certain inflammatory toxins of the bacteria and that these bacterial products originate in the area of infection and result in an inflammatory reaction. The intensity of inflammation depends directly on the quantity, the virulence and the production of toxins by the type of bacteria concerned in the focus of infection. Thus the degree of infection is in simple proportion to the bacteriotoxic damage of the tissues. The effect of an immune serum on the inflammatory toxin of the cerebrospinal fluid used in experiments was observed in intrathecal injection of a mixture of both these substances after an incubation period of two days. The action of the serum was investigated likewise in vivo. The commercial immune serums did not exert any action either in vitro or in vivo on the bacteriotoxic inflammation. No unspecific serum effect on the reactive tissue inflammation could be observed. The tissues did not become accustomed to and no "active immunity" of the tissues against the inflammation toxins was produced by the toxins themselves or by specific vaccine. Thus the inflammation toxins should be considered as simple cellular poisons without the antigen property, and serum therapy cannot be considered effective for passive protection against infection from bacteriotoxic inflammation.

Symptoms of Typhoid—Von Drigalski and Martin state that there is no one symptom present in all of the cases of typhoid. The temperature curve and eosinopenia are the most trustworthy. Leukopenia and the Gruber-Widal reaction are positive in about three fourths of all cases. Bacilli were demonstrated in feces and urine of about two thirds of the cases. Roseola was next in frequency, followed by enlargement of the spleen, Ehrlich's diazo reaction and bradycardia. Generalized enlargement of the lymph nodes, initial neuritis in the area of the left brachial plexus and pronounced splenomegaly in the absence of almost all important symptoms of typhoid were observed in individual cases. The clinical picture of typhoid may be atypical because of the absence of classic symptoms and because of the presence of unusual symptoms. It may present a picture entirely different from that given in textbooks.

Increase in Perforation of Peptic Ulcer in Wartime—Surgical intervention for perforating peptic ulcer was performed at the General Hospital of Wiener Neustadt in from 3 to 4 cases per month after the outbreak of the war as contrasted with 1 to 2 operations in peacetime. Instances of perforation of peptic ulcer were nearly doubled. They were acute in the majority of the cases and occurred exclusively in men. Change of living habits resulting from wartime production, change from day to night shifts and vice versa, irregular and cold meals, close attention to work, and excitement caused by war affect the vegetative system. Perforations occurred predominantly in heavy smokers. Nicotine by its effect on the vegetative system may be of foremost importance in the pathogenesis of peptic ulcer.

Book Notices

Psychosomatic Medicine The Clinical Application of Psychopathology to General Medical Problems By Edward Weiler M.D. Professor of Clinical Medicine Temple University Medical School Philadelphia and O. Spar von Enck M.D. Chief of Psychiatry Temple University Medical School Cloth Price \$8 1p 687 with Illustrations Philadelphia London W B Saunders Company 1943

For the first time the subject of psychosomatic medicine has been brought before the medical profession in a clear, concise and informative discussion. The opening chapter gives the reader a concept of the problem. As the authors aptly point out in the summary, "The study and treatment of illness constitutes much more than the investigation and eradication of disease. The chapter on personality development and psychopathology is exceedingly well handled and instructive. From there on the authors take up the various systems of the body in relation to the emotional disturbances and the end results of hypertension and hypotension. These manifestations are presented from the point of view of case history along with suitable discussions. The treatment is handled in a very composite manner. The book as a whole serves an important need of the medical profession and it should be of particular interest to teachers in medical schools who must become thoroughly familiar and imbued with the importance of psychosomatic medicine. Therefore it is highly recommended as one of the important contributions to the medical literature of the year."

Clinical Significance of the Blood in Tuberculosis By Gullit Lindh Muller M.D. Pathologist and Director of Laboratory New England Hospital for Women and Children Boston Cloth Price \$3.50 1p 316 with 19 Illustrations New York Commonwealth Fund London Oxford University Press 1943

This book, on the clinical significance of the blood in tuberculosis is more than a mere description and tabulation of the various hematologic manifestations of the disease. In fact, it often goes rather far afield in the discussions relating to such features as the sedimentation rate and the various hematologic indexes. However this is by no means a disadvantage since one may obtain in this book an exceedingly well documented and complete description including historical summaries, of the Arneeth count, the Schilling hemogram and the monocyte-lymphocyte ratio. Since good descriptions of these subjects are often obtainable only in scattered form elsewhere this is very helpful to the interested student.

Excellent descriptions of the bone marrow, the various cellular reactions to disease, the monocyte and other subjects are presented together with well balanced commentaries on the various indexes which have been offered as short cuts to the diagnosis and prognosis of tuberculosis. The attempts of Sabin, Doan and Cunningham to elevate the monocyte, supravital staining and the monocyte-lymphocyte ratio to high standing are thoroughly investigated, the conclusion being made that an increase, decrease or lack of change in the number of monocytes per se gives but little indication of the state of the tuberculous process. The status of the lymphocyte offers a somewhat better indication since these cells become increased with healing and vice versa. Supravital preparations—and this is the reviewer's experience as well—have been greatly overrated. They are furthermore stated to be time consuming, not permanent and limited as to time of observation.

All the numerous hematologic tricks which have been proposed for the study of tuberculous blood are thoroughly and wisely discussed such as eosinophilia, absolute vs relative numbers of leukocytes, study of immature polymorphonuclears, toxic changes and the reaction of the blood to tuberculin. In addition the anemia, the leukemoid reactions which occasionally occur especially in miliary tuberculosis and hemorrhagic manifestations are discussed. The reviewer hastens to reemphasize Dr Muller's statement that little (I would say nothing) can be gained by the use of expensive liver extracts in the treatment of the anemia of the disease. If this product should be used only for pernicious anemia which is really the sole disease in which liver extract is indicated, imagine how sharply the sales of the product would be curtailed.

A large section of the book is devoted to the sedimentation rate, fifty-five pages in all being given over to a general discussion of this important test. The numerous techniques are

adequately described and criticized, and a new correction table is presented. Unfortunately there is no general discussion of the value of the test in various phases of the disease. One also misses at the end of the book a general, over-all view of the value or lack of value of the various tests. In other words, the details are beautifully painted in, but there is lacking a general integration of the whole picture with the result that the reader does not get a unified conception of the author's conclusions. However of the various hematologic components listed—increased sedimentation rate, neutrophilia, shift to the left, monocytosis, lymphopenia and lymphocytosis, eosinopenia and eosinophilia—the most important to watch from a prognostic standpoint are the sedimentation rate, the shift to the left and the lymphocyte percentage.

The book is well written and printed. The studious and exhaustive nature of the monograph is attested by the excellent bibliography which contains six hundred and four complete references.

A Family of Thirty Million The Story of the Metropolitan Life Insurance Company By Louis J. Dublin M.D. Third Vice-President and Statistician Metropolitan Life Insurance Company Cloth Pp 496 with Illustrations New York Metropolitan Life Insurance Company 1943

This is the history of the Metropolitan Life Insurance Company but it is more than that. It is also the history of insurance and its growth with the growth of the nation, its troubles and trials, its shortcomings and its triumphs and, most of all, its contributions to the nation's financial stability, social development and public health. The author writes exhaustively of the growth and development of the Metropolitan but deals generously also with other companies competing in the same fields. The book reflects more than mere pride in financial success, though there is plenty of that, for the Metropolitan is not only the world's largest insurance organization but the world's largest financial corporation. Through the book shines the spirit of the men who made Metropolitan great because they were more than shrewd businessmen and canny financiers. They were that but they were men of broad vision too, who saw that nothing makes a man or an organization great more surely than to be of service to other men. The history of Metropolitan as set forth in this book could be summed up in one simple statement—it has consistently given more than it was compelled by contract to give to its policyholders and to the nation. This is manifested in repeated liberalization of contracts, often retroactive, in generous treatment of lapsed and reinstating policyholders, in prompt handling of claims and in a general attitude of liberality toward all proper claims.

Of special interest to physicians is the chapter on relationships to medical science and public health in which fields the Metropolitan has contributed generously through grants for research and demonstration and participation in numerous projects. The Welfare Division, making nursing services available to its millions of industrial group and intermediate policyholders and contributing billions of free pamphlets to health education as well as numerous exhibits, loan films and a help by correspondence service for school teachers is typical of the spirit of service which has been evident throughout the history of the Metropolitan. That this has been profitable in no way detracts from its significance since the mutualization of the company voluntarily carried through by its stockholders, the benefits of profitable operation have accrued to all the policyholders.

The book itself, aside from the history of a great institution which it portrays, is interesting. Dealing with numerous figures, many personalities out of the past and numerous matters which might easily have become dull it nevertheless contrives to be interesting throughout and sometimes exciting. Every chapter, every paragraph hews to the line, telling a story or service. That the author has been a part or much of this history has rubbed shoulders with those who have made and are making it and has made some of it himself—the Statistical Department and its valuable publications, notably the *Statistical Bulletin* which is said to have more readers than any best seller—enables him to write with authority and enthusiasm.

The book is also a mine of information about insurance in terms which the inexperienced reader can readily understand.

It is, in addition, an important social document. It offers the institution of life insurance and collateral lines such as accident, health, hospital expense and surgical expense insurance as America's answer to the problem of social security. It demonstrates how even the poor man, through industrial or group insurance, can provide means to keep him off the relief roll and to maintain his self reliance and self respect. This philosophy is perhaps best stated in the words of the preface: "At this time in our history, when the desire for security is greater than ever before, it is hoped that this volume will reflect what the American people have done through life insurance to provide financial protection for themselves. They have achieved this security to a greater degree than any other people, achieved it voluntarily, and through institutions of their own making. This is an American tradition. They have not depended upon government subsidy but have themselves taken the initiative. Americans apparently prefer this method, which takes into account individual needs and relies on the sense of obligation of the head of the family to look after his own."

Kitchen Strategy Vitamin Values Made Easy By Leona M. Bayer M.D. Assistant Clinical Professor of Medicine, Stanford University School of Medicine San Francisco and Edith S. Green B.A. Paper Price, \$1.50 Pp 107 with illustrations by Antonio Soomayor San Francisco The Authors 1943

This is a ring binder looseleaf booklet dealing with the practical aspects of choosing, buying, preparing and cooking foods that will supply the essentials of good nutrition and still make the family think they are just eating food—a consummation devoutly to be wished in these diet conscious days. It is attractively embellished with cartoons. The section on menus for common ailments should either have been omitted or have been amplified. In the hands of the lay person, for whom this booklet is obviously intended, this section might suggest that these are the only menus, whereas they are samples. The author explains this, but the criticism holds nonetheless. There are excellent chapters on substituting more common for scarcer foods, these should prove invaluable if rationing really grows severe. All in all, the book may be recommended, with the possible exception of pages 33 to 41, for the reasons set forth.

Medical Biochemistry By Mark R. Everett Ph.D., Professor of Biochemistry University of Oklahoma School of Medicine Oklahoma City Medical Students' Series edited by Fred C. Zapffe Secretary Association of American Medical Colleges Chicago Cloth Price \$5.75 Pp 694 New York & London Paul B. Hoeber Inc., 1942

This book, which is one of several in the Medical Students' Series, is intended to present "a modern, concise and correlated survey of biochemical knowledge for students of medicine and allied subjects." It is supposed to be part of "a new approach to textbook writing," as is envisaged in the Medical Students' Series, books written specially for students rather than for academic didactics alone. The contents include discussions of acid-base relations, colloids, enzymes and oxidation, digestion, lipids, carbohydrates, proteins, prosthetic radicals of nucleoproteins and chromoproteins, inorganic substances, vitamins and avitaminoses, hormones and endocrinoses. An addendum offers a guide to biochemical literature. There are two indexes, a general index and an index to tables, both are quite complete and useful.

The editor of this series, Fred C. Zapffe, states "So much time, thought and effort have been put into this project that it should warrant a fair trial by all those who are competent to pass judgment—teachers and students in the fields covered." The preparation of books intended primarily for students is commendable, often there are too few textbooks with this objective in a given field. Sometimes, however, such textbooks present material which is best left for other sources, medical biochemistry is one of these. It presents many excellent digests on biochemical questions but occasionally borders too closely on problems such as avitaminoses and endocrinoses, which are best left to other special treatises. There is no denying that a knowledge of the chemistry of the body's functionings is as essential as a knowledge of the pathologic changes and accepted treatments, otherwise it would be difficult to understand and treat properly many diseases, especially those due to deficiencies. However, if this book is "to offer the medical student a volume which presents the basis of the subject in such form and degree of detail as he can absorb in the time allotted," the contents

should be reserved for biochemical considerations with only sufficient reference to diseases and pathology to orient the student with the reasons for teaching and learning such subjects as biochemistry. Apart from this criticism, the book, if used as a book of this nature should be used, is one that can be useful for the teacher and student. It is easy to read and has a sufficient but not depressing number of formulas and tables to make clear most of the author's statements.

Cancer Control The What Whither How Edited by Channing C. Simmons Paper Price 50 cents Pp 86 Boston Massachusetts Department of Public Health Division of Adult Hygiene 1943

This is a publication of the Massachusetts Department of Public Health in close collaboration with the state medical society. It deals with the cancer control program in the state, with special attention to health education and its possible contribution to the solution of the cancer problem. The committee seems either to be at a loss what to say about health education and cancer control or unwilling to say what it thinks. Part III of the report, dealing with how cancer education should be conducted, "has not been written. It is hoped that several committees will devise outstanding educational methods which will warrant being included in this section."

Other chapters deal with cancer prevention as far as preventive measures are known, with methods of treatment and with research. This eminently erudite and dignified publication will have a small circle of interested—previously interested—readers but will not do much to bring knowledge of cancer to the man in the market place or his wife in the home or the factory—which is where cancer education has to go. It has to go there in much less dignified garb and in much plainer, easier, simpler, more understandable terms—and much briefer.

Biological Symposia A Series of Volumes Devoted to Current Symposia in the Field of Biology Edited by Jacques Cattell, Editor of the American Naturalist and American Men of Science Volume IX Sex Hormones Edited by F. C. Koch, Frank P. Dixon Distinguished Service Professor and Chairman of the Department of Biochemistry of the University of Chicago and Philip E. Smith Professor, College of Physicians and Surgeons Columbia University New York Cloth Price \$2.50 Pp 146 with illustrations Lancaster Pennsylvania Jacques Cattell Press 1942

This book is the ninth in a series of volumes devoted to current symposiums in the field of biology. Edited by men renowned in the respective fields, the series is one that should be available in all reference libraries. The present volume, which includes the papers from the symposium on sex hormones presented at the fiftieth anniversary celebration of the University of Chicago in September 1941 and the symposium on hormonal factors in sex inversion presented at the annual meeting of the American Association of Anatomists in April 1942, adds to the credit of the series. The contents include discussions of the comparative biology of testicular and ovarian hormones by C. R. Moore, the comparative metabolic influences of the testicular and ovarian hormones by A. T. Kenyon, the metabolism of estrogens by E. A. Doisy, the excretion and metabolism of male sex hormones in health and disease by F. C. Koch, sex inversion in the plumage of birds by C. H. Danforth, sex inversion in the amphibia by R. R. Humphrey, the effects of sex hormones on embryonic sexual structures of the rat by R. R. Greene and hormones and experimental modification of sex in the opossum by R. K. Burns Jr. While the presentations are as general as would be expected in such symposiums, most of them can be read with interest and profit not only by the specialist in this field but by others if they possess even a spark of interest in endocrinology.

Nursing History in Brief By Minnie Goodnow R.N. Second edition Cloth Price \$2.25 Pp 338 with 103 illustrations Philadelphia & London W. B. Saunders Company 1943

This is designed as a textbook for short courses in nursing history (fifteen hours or less). It is well organized clearly and interestingly presented and well illustrated. It begins with the story of nursing efforts among primitive peoples and includes material as recent as the nursing records of the current war. A general historical chronology and a chronology of nursing history are given. Review questions are presented at the end of the book, not chapter by chapter. There is an excellent index.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

SKIN PEELING FOR ACNE

To the Editor—A young girl has severe acne which has resisted all routine therapy. A course of x-ray treatment left deep pitting of the lesions. The family has asked my advice concerning skin peeling. I intend to start with 3 per cent sulfur and salicylic acid beginning with a small area. I have a good idea of the technic but kindly inform me of the exact procedure and if there is any better medication than the one I have mentioned.

George H. Jantzen, M.D., Queens Village, N. Y.

To the Editor—A young girl in my practice has had serious scarring of her face from acne. She has had x-ray treatment and deep red scars are present. The question arises as to whether her face should be peeled after school is over. Would you please advise me as to what benefit might be expected from peeling her face after having gone through with x-ray treatment of her skin? Hubert B. Haywood, M.D., Raleigh, N. C.

ANSWER—Skin peeling is not used as generally in this country as in Europe because of the dangers. When done carefully it gives satisfactory results. The chief dangers include production of an acute dermatitis in a skin sensitized to one of the drugs used, or an overeffect causing a chronic erythema or even necrosis of the skin and of absorption of the drug resorcinol or betanaphthol harming the kidneys. These may be guarded against by preliminary patch tests by a cautious approach and by careful and repeated examination of the urine. Brocq's formula for a keratolytic slake for severe acne of the trunk is as follows:

	(in gr Ce)
Re. arcinol	
Camphar	aa 10.00
Polash soap	15.00
Precipitated sulfur	30.00
Prepared chalk	5.00
Petrolatum	30.00

Formulas for other mixtures may be found in A Text Book of Dermatology, by J. Darier (authorized translation of the second French edition, edited with notes by S. Pollitzer, Philadelphia and New York: Lea & Febiger, 1920, p. 732).

A good description of the technic is given by Kren (Kosmetische Winke, Vienna and Berlin, J. Springer, 1930, p. 25). He refuses to attempt this treatment for any one with impaired kidneys and insists on a careful urinalysis before each application of the exfoliating paste which is composed of:

	Gm or Ce
Betanaphthol	10.00
Flowers of sulfur	40.00
Green soap	
Petrolatum	aa 25.00

If the yellow mass turns brown because of the effect of light on the betanaphthol, no harm is done. Only part of the face should be treated at a time: cheeks and chin for instance, the first time; nose and forehead at a later time. The part to be treated is first washed with benzine to remove fat and then the paste is applied about 2 mm thick. The clothing must be protected since the paste causes spots. A moderate burning sensation is experienced but it lasts only a few minutes. After the paste has remained for from twenty to thirty minutes it is removed with dry cotton or fine gauze, care being taken to remove it all. No water or soap is allowed. The skin will be slightly reddened but this clears in a few hours.

On the next day, or even after twelve hours, the process is repeated and each day again until slight exfoliation begins. The urine should be examined repeatedly to guard against kidney irritation. If albumin or casts appear the treatment must be given up.

One per cent salicylic acid in alcohol applied night and morning is the only washing this part of the skin is allowed. After peeling begins, this solution is to be dabbed on several times a day. After about five days' use of the exfoliating paste the process will be complete in three or four days. Left on the skin too long the paste may cause ulceration. The whole procedure, applied to the whole face in two separate treatments, takes a little more than two weeks.

A milder, more easily controlled procedure has been used for a number of years for the same purpose with excellent results in many cases. This is the application of a slush or solidified

carbon dioxide and acetone. Recently sulfur has been added. Karp, Nieman and Lerner (Cryotherapy for Acne and Its Scars, *Arch. Dermat. & Syph.* 39:995 [June] 1939) describe the technic as follows:

The apparatus consists of a large clay mortar and pestle, solid carbon dioxide, acetone, precipitated sulfur, absorbent cotton, a square of gauze and a wooden tongue depressor. Approximately 5 ounces (140 Gm.) of solid carbon dioxide is placed in a large clay mortar and ground to a fine powder. Acetone (dimethylketone) is carefully added with constant stirring until a smooth paste is obtained. Then with a wooden spatula approximately ¼ ounce of precipitated sulfur is added until a light yellow mixture is formed. If necessary a few additional drops of acetone may be added.

About one third of the paste is placed on a tampon of absorbent cotton, covered with a square of gauze and applied under moderate pressure to the most prominent lesions. The tampon is then immersed a second time in the paste. At this stage the addition of a small amount of acetone is usually necessary. The carbon dioxide paste is now applied directly to the skin. The application is made without pressure, and the entire face is covered with rapid friction. The resulting deposit of sulfur is allowed to remain on the face for approximately twenty minutes after the treatment. Immediately after application erythema and slight edema appear, which last about two or three days and are followed by mild exfoliation of the epidermis. Applications are repeated at weekly intervals. Note: "Acetone is inflammable." They report excellent results but warn against the danger of using it on atrophic skin or on melanomas. Even when roentgen treatment has been mild it adds to the risk of excessive reaction to the cryotherapy. They believe that the improvement of scars is due to the lessening of their sharp outline and increase of circulation and skin tone.

Dobes and Keil (Treatment of Acne Vulgaris by Cryotherapy [Slush Method], *ibid.* 42:547 [Oct.] 1940), applying it generally had good results in 16 of their 69 papulopustular cases but by applying it locally to individual nodules in the cystic cases they cleared up a much larger proportion. They encountered some difficulties. Among their patients were two with cold allergy who responded to the treatment with immediate urticaria and a burning sensation lasting several hours. Another patient reacted to cold even cold weather with a new crop of pustules. A severe edema of the face occurred in 1 girl and lasted two days. A Negro developed a patch of depigmentation lasting for months. Deeply tanned white persons showed no such result. From a trial application of the slush 1 patient developed a blotchy purpuric erythema ending after a month in mixed hyperpigmentation and hypopigmentation. Thus the method has a limited field, taking the place of the old peeling methods because of its deeper action and greater ease of control. Dobes and Keil are not much impressed with the improvement of scars. They quote Karp's opinion that at least eight months of treatment is needed to show decided improvement of acne scars, while those resulting from smallpox should be given seventy-five to eighty treatments. They omit the sulfur from the slush for the treatment of scars.

So far no one has devised an objective method of measuring the results of treatment of multiple small scars such as those occurring as a consequence of acne. There is no doubt however that the impression that the scars are less noticeable in spite of the skepticism of the physician has a beneficial effect on many patients. Karp, Nieman and Lerner warn against the too energetic treatment of scars. Repeated mild treatments give the best results, and time must be allowed for the effects of one treatment to subside before repeating it. These rules should apply also to the chemical peeling process.

PROBABLE ALOPECIA AREATA OF BEARDED AREAS

To the Editor—A man aged 50 has an area of alopecia on each side of the cheek. The duration is about two years and the areas are gradually increasing in size localized to these two spots. The physical examination is essentially negative. Previous physicians consulted had informed the patient that there is no treatment effective. I shall appreciate advice as to investigation and treatment. Esther Tuttle, M.D., New York.

ANSWER—The inquirer does not give any details about the patches of alopecia. It is assumed that there has been neither scar formation nor atrophy produced and that there is no visible inflammation present. Without the presence of inflammation one can discard such possibilities as ringworm infection of the beard and coccogenous sycosis. Tertiary syphilis, lupus erythematosus and iatrus can be ruled out because there is no scarring or atrophy. The probable diagnosis therefore, is alopecia areata.

Alopecia areata is rather common on the scalp but appears less frequently at other sites. The bearded area however is

not rarely involved. The characteristics of the disease here are no different in any essentials from those on the scalp. The hair falls to leave a clean, noninflamed patch or patches and there is no progression to scar formation. The borders of the patches are fairly well defined and regular. In an actively forming area there may be found the well known "exclamation point" hairs showing narrowing at the base. One would not expect to find such hairs at the edges of patches of two years' duration.

Alopecia areata seems to take a course which often extends from several months to two years with extremes in some of much shorter and longer duration. Thus one must be careful not to draw unwarranted conclusion from the results following any special regimen in a particular case. In general the outlook for any patient depends on the extent of the alopecia and the age of the patient. Younger ones do better, so that a middle aged person such as the one under consideration would not be expected to do well. Those who get well have regrowth of hair in any one patch relatively early, though prolongation of the process takes place by new patches forming. In a middle aged man who has the same areas present without regrowth and with spreading of their borders the prognosis is bad. If there are any hairs present even to the finest lanugo, it is worth treating the patient. It is possible that this effort may help to stay the progress of the disease.

The entire patient should receive attention. Many believe that alopecia areata is mediated by mental stress or through nervous reflexes. This should be explained to the subject to gain his cooperation in the attempt to resolve worries and irritations. He may need rest and reduced responsibilities. Sources for reflex stimuli such as infections of sinuses or teeth should be hunted and eradicated. Anemia or indications for tonics may be present. Some observers laud hydrotherapy. Local measures include the application of materials to stimulate the sites of alopecia. A popular one is the painting with liquefied phenol. This produces a whitish parboiled appearance, at which time alcohol is quickly applied to neutralize the phenol. Recovery from the induced inflammation takes place in five days or a week, when the applications are remade. These reapplications may be given over a prolonged period. Cutler's fluid may be used instead of phenol. Cutler's fluid consists of equal parts of liquefied phenol, tincture of iodine and chloral hydrate. Numerous other applications of similar character are recommended, but these probably have no greater merit. Ultra-violet ray applications are useful and popular. Frequent shaving makes the patches over the beard less conspicuous.

THROMBOSIS OF SAPHENOUS VEIN AFTER HYSTERECTOMY

To the Editor—A hysterectomy was performed on March 24, 1943 on a woman who is 45 years of age. She developed phlebitis in her right internal saphenous vein. She had a slight elevation of temperature and palpable beating of that vein. The temperature subsided in about three days, and at present there is little tenderness along the saphenous vein, but she has a great deal of tenderness in the calf region of her leg. I treated her conservatively and we have a difference of opinion as to whether she is a proper subject for injection of procaine hydrochloride into the lumbar region on that side. Kindly advise me what is considered the best treatment for this condition today. M D, Connecticut

ANSWER—It is impossible to give a categorical answer to this query, since it is uncertain from the description as to what type of thrombosis developed after hysterectomy. Postoperative thrombosis affecting the saphenous vein alone is infrequent unless there are preexisting varicosities of the saphenous vein. If this should be the case, a ligation of the saphenous vein and its tributaries at the saphenous femoral junction is the method of choice. The pain in the calf demands the consideration of the possibility that the muscle veins of the calf may also be involved. This type of thrombosis often extends to the deep veins of the lower leg and may be the source of embolism. A slight cyanosis in the dependent position and pain in the calf or popliteal fossa on dorsiflexion of the foot are further suggestive findings of deep venous thrombosis of the lower leg. If facilities are available a radiopaque solution may be injected into a small superficial vein on the foot and the patency of the deep veins visualized. If a diagnosis of deep venous thrombosis of the lower leg can be made, the best current opinion is that a ligation of the femoral vein below the profunda is indicated since it prevents embolism. This is especially true of patients close to 50 years of age, since the incidence of embolism rises after the fifth decade. If prothrombin determinations can be made, the extract of spoiled sweet clover (dicumarol) can be cautiously administered to offset the increased clotting tendency of the blood and prevent further spread of thrombosis.

The procaine hydrochloride injection of the lumbar sympathetic chain relieves the pain and the acute edema of a deep thrombosis. It is most useful in the first few days after the onset and seems less and less useful after the early pain and edema have subsided. Its purpose is to inhibit a vasospasm of the small arterioles and venules, which is due to an autonomic reflex originating in the thrombosed vessel. If the thrombosis is chronic, if there is no pain and edema, the nerve block is unnecessary.

TREATMENT OF FRACTURES ABOUT ELBOW

To the Editor—I was taught to put up fractures around the elbow in the "Jones position" the arm acutely flexed, the thumb and fingers grasping the throat. This method, it seems to me, has objections. The hand cannot be used, and the amount of dressings required is considerable and some what difficult to apply and to keep in place. In the summer months such a dressing is hot and causes free perspiration followed by irritation of the skin, as well as some bad odor. The shoulder and hand cannot be exercised. In a small town I do not have the opportunity to see many injured elbows. However, I have recently seen a severe injury to the elbow in a 9 year old girl. I put her arm up according to my own ideas, and I got a perfect result—no deformity and complete restoration of function. Whether the method is old and I just haven't heard about it or seen it described in the textbooks, I don't know. The method is simplicity itself. I flexed her arm just as I would have done in the Jones method. I held it in this flexed position by passing an adhesive strip in such a way as to go round the forearm just below the wrist and the upper arm just below the axilla. I put a small piece of cotton in the fold of the elbow—and that was all there was to it. The patient could exercise her fingers and shoulder, could even use her hand for some things. The skin is easily reached for cleansing purposes, the dressing is easily and quickly applied and is a minimum of trouble to change. Free ventilation is allowed between the arm and the body. If this method is wrong, I should like to know it. If it is right and has not already been described, I should like others to know about it.

Emory R. Park, M.D., La Grange, Ga.

ANSWER—The "Jones position" of the forearm flexed directly over the arm as the axes of the two coincide is orthodox and widely used. It does not effect or maintain reduction of all types of fractures about the elbow. It is described in textbooks. The reduction procedure for supracondylar fractures of the humerus, mostly in adolescents, is slight extension of the forearm during traction on it, followed by flexion into position with axes superimposed. No effort is made to have the fingers clutch the throat, as that may cause rotation of the forearm and result in incomplete reduction. The reduction is checked by x-ray examination in two planes, anteroposterior and lateral, through the elbow. (See Primer on Fractures.) This position may be maintained by a posterior molded plaster splint from the upper arm to the base of the fingers, which leaves the shoulder free for motion and the arm for abduction. If the wrist is allowed too free motion it may cause displacement of the fragments of the humerus by rotation of the forearm. The arm, thus splinted, may be carried in a sling and need not cause skin irritation from sweating, as the whole arm can be lifted and held up in abduction without disturbing the reduction at the elbow. It is possible, in the small arm of a child, to hold this position with adhesive tape with a small sterile pad in the antecubital space, but the heavier arm of an adult may slip out of the adhesive or by its weight cause skin irritation. The method described in the query was perfectly adequate. It is not new and was popularized by Ashhurst thirty years ago. After any of these dressings, it must be known that the circulation (radial pulse) remains normal in the limb.

ACROCYANOSIS AND AUTOAGGLUTINATION OF RED CELLS

To the Editor—A case of clinical acrocyanosis recently came into our hospital. When a routine venipuncture was performed for blood studies it was noted that the blood clotted so quickly that examination of the blood was impossible. When blood was drawn into ordinary red blood cell and white blood cell pipets the same phenomenon occurred in the chamber of these pipets. Microscopic examination of these clumps of cells revealed that the red blood cells were massed together either in rouleau formation or simply massed together in nonrouleau formation. No fibrin was present. Heating the chamber of a pipet containing these clumps of red blood cells resulted in the disintegration of the clumps, and microscopic examination then revealed perfectly normal appearing erythrocytes and leukocytes. The red blood cell and white blood cell counts were normal. In examining the literature I have found no definite statement of the cause of acrocyanosis. I should appreciate information from you as to what is now considered the most likely explanation of acrocyanosis and whether the herein described phenomenon has ever been described in association with acrocyanosis. Lieutenant M. C., A. U. S.

ANSWER—Autoagglutination or "cold" agglutination of red blood cells has been observed in a number of persons (Walther *G. Folia haemat.* 38:281 [July] 1929). McCombs and McElroy *Arch. Int. Med.* 59:107 [Jan] 1937 reported a case in which autoagglutination was associated with acrocyanosis.

and cited 5 additional cases from the literature. Two of the authors advanced the hypothesis of autoagglutination as a cause of Reynaud's disease. Two more cases were reported by Benians and Frasby (Reynaud's Syndrome with Spontaneous Cold Hemagglutination, *Lancet* 2 479 [Oct 25] 1941). Autoagglutination in a patient with acquired hemolytic anemia has been observed. On exposure to cold, the face and hands become definitely cyanotic.

It is apparent that vasoconstriction which is usually considered to be due to vasospasm, may also be related to autoagglutination.

PENILE ULCERS

To the Editor—In a genitourinary clinic and genitourinary ward recently smears in 4 cases of extraurethral lesions were positive for gram negative diplococci. One patient had two small abscesses of the shaft of the penis and smears were repeatedly positive for gram negative diplococci. No history of previous gonorrhea or recent urethral discharge coeci. Cultures were oxydase positive. The second patient could be obtained. Cultures were oxydase positive. The second patient had small penile ulcers with repeated negative dark fields. Smears stained with Gram's stain showed gram negative intracellular diplococci. Culture from lesions gave positive oxydase and transplants to sugar mediums were positive for *Neisseria gonorrhoeae*. The third and fourth patients had penile ulcers from which smears showed extracellular gram negative diplococci. Cultures and further studies are being made. I am interested in opinions as to the possible causation of these acute penile ulcers. In all cases the lesions appeared from four to ten days after intercourse and this incubation period plus the data heretofore mentioned makes me feel that the gonococcus is the causative agent of many penile lesions previously classified as cause undetermined.

Captain M C A U S

ANSWER—Several cases similar to these have been reported in the British literature in which it was thought that the penile ulcers were due to *Neisseria gonorrhoeae*. However since gram positive coeci in certain lesions appear gram negative and even intracellular in gram stained smears it would appear that the lesions described may not be caused by *N. gonorrhoeae*. The positive oxydase reaction is also given by some types of micrococci and other bacteria. Small gram negative diplococci or coccobacilli formerly called Gurd's diplobacilli are occasionally found in eroded areas in the female vagina and can infect abraded areas on the shaft of the penis. One should subject the cultures of coeci to all determinative criteria before actually describing the condition as extraurethral gonococcal ulcers.

INTRAVENOUS INJECTION OF AIR

To the Editor—I should like to establish whether the blood stream of the average human being can absorb 1 cc. of air which is injected into it under 30 pounds of pressure. This question arises from certain inquiries about a new development project and it would be most desirable if an answer could be secured as soon as possible.

Clark D Bridges Industrial Hygienist Chicago

ANSWER—The effects of the injection of 1 cc. of air under 30 pounds pressure into the blood stream of the human being would obviously vary with the site of injection. Injection into one of the systemic veins would probably not give rise to serious consequences, since the oxygen would be taken up mainly by the hemoglobin and slightly by simple solution in the venous blood and the nitrogen would be filtered out by the pulmonary capillaries. However, rarely one or more bubbles of nitrogen will pass through the pulmonary circulation to the left heart chamber and if a nitrogen embolus should lodge in one of the coronary arteries or one of the arteries supplying the vital medullary centers the consequences would be serious or even fatal. Usually, however, much larger quantities of air intravenously are required to produce death by air embolism. Injection of the air into the left heart chamber would certainly afford good opportunity for coronary embolism and fair opportunity for medullary embolism. Likewise injection into one of the main carotid arteries would likewise entail definite risk of medullary embolism. Injection of the air into other systemic arteries would involve less risk. Obviously 1 cc. of air under a pressure of 30 pounds would expand to approximately 3 cc. when introduced into a vein and to only slightly less than 3 cc. if injected into an artery. The injection of the air under the pressure mentioned might lead to rupture of the vein or even the artery at the site of the injection although this would be unlikely. The absorption or solution of the nitrogen would be slow under normal circumstances, although previous denitrogenation of the human subject by the breathing of pure oxygen would, of course, permit rapid solution of the nitrogen in the blood and tissues.

INHERITANCE OF PSEUDOHYPERTROPHIC FORM OF MUSCULAR DYSTROPHY

To the Editor—A healthy white woman is gravid for the first time since her first pregnancy twelve years ago. Her first born son has a pseudohypertrophic form of muscular dystrophy. She fears that this offspring may be afflicted with the same condition. What is known about the hereditary aspect of this disease? What should one advise this patient about continuing her pregnancy?

M D, Virginia

ANSWER—The pseudohypertrophic form of muscular dystrophy is considered a hereditary disease. When it appears in successive generations in a family, it has mendelian dominant characteristics. In this type of inheritance the chances of it appearing in sibship is almost 50 per cent, the sexes usually being affected with equal frequency. If, on the other hand, the disease has not occurred in previous generations and thus may be looked on as a recessive factor, the chances of inheritance are less. In spasmodic cases of this type the disease is more prevalent in the male in a frequency of about three to one. In order, therefore, to estimate whether a second child would have pseudohypertrophic muscular dystrophy, when the first child was so afflicted the history of the disease in previous generations should be obtained. Advice with regard to continuance of the pregnancy cannot be given in a categorical manner. The facts however, as known may be placed before the family.

DIAGNOSIS OF RECURRENT SKIN LESIONS IN WINTER

To the Editor—A man aged 51 states that twenty-five years ago following exposure to cold he sustained a severe case of frostbite involving the hands, forearms and both earlobes. Since that time starting in late September and extending to early May a dermatitis involving the hands, forearms and earlobes makes its appearance. The skin hardens, cracks easily and is reddened and there are scattered papular lesions. Glycerin applied to the exposed parts appears to offer systemic relief although it does not cause the skin lesions to disappear. Various possibilities such as occupational dermatitis, soap dermatitis and water dermatitis were considered. He has changed his occupation and at present is a supervisor and does not do manual labor. He does use a castile soap and avoids wetting his hands as much as is consistent with body cleanliness. The blood serologic reaction, sedimentation rate, platelet count, cell count and renal function tests are negative. Could you describe the physiologic basis for the disorder described and also plan a course of therapy? Is there merit to the therapy of ionization using salicylic acid, histidine or sodium chloride as an electrolytic base?

Charles S Mirkin M D New York

ANSWER—The possibility of a seasonally recurring dermatitis venenata or contact dermatitis has been entertained with good reason. The history of onset after freezing of the parts and the recurrence of the lesions during the colder seasons suggest the diagnosis of pernio. There are several varieties of pernio, two of which are called lupus pernio. The first or chilblain lupus with which Hutchinson's name is linked is a form of lupus erythematosus. It consists of infiltrated erythematous patches which become worse in the winter. The lesions are bluish red or violaceous which first resemble chilblains and discoid lupus erythematosus. The second type of lupus pernio the one associated with Besnier's name is classified with sarcoidosis. Its lesions occur symmetrically on the ears and face, hands and feet and are thickened bluish red patches. They show small brownish red nodules by diascopic pressure. Small dilated blood vessels are present and many manifestations of sarcoidosis may be associated such as changes in the small bones and enlargement of the lymph glands. Both kinds of lupus pernio do not disappear entirely in the summer though they may improve considerably. In the case under consideration the skin changes apparently disappear entirely during the warmer months. It is more likely, therefore, that the condition is ordinary pernio or chilblains. It disappears entirely in summer and is based on a poor circulation. The lesions are various shades of red, feel tender and may burn or itch. They feel cold to the touch.

This patient should be investigated for tuberculosis. His circulation should be improved by physical therapy, exercise and massage. Warm clothing should be worn and the parts protected by cotton batting and local applications. Dusting powders of boric acid, talcum or the parts may be painted with ichthammol. The administration of arsenic is helpful and may be given in the form of solution or potassium arsenite or the asiatic pill.

POSSIBLE KIDNEY DAMAGE AND LATE HYPERTENSION
FROM KEROSENE

To the Editor—A white, single woman aged 25 was seen four months ago for the first time because of an attack of dyspnea and nausea. She then weighed 185 pounds (84 Kg) and now weighs 170 pounds (77 Kg). She had an elevated blood pressure of 240/120, which has remained approximately the same. Her urine showed 4 plus albumin, intermittently since then the urine has been completely free from albumin. Blood chemistry showed nonprotein nitrogen of 42, creatine 1.3 and cholesterol 220 mg. I do not believe any hyperthyroidism exists, basal metabolic tests read plus 23 and plus 26. Cystoscopy showed a normal bladder and bladder mucus. A number 6 French catheter was inserted into each kidney pelvis without resistance, and no residual urine was found. Specimens were clear. A plain x-ray film showed no radiopaque stone in the kidney, ureter or bladder, and bilateral pyelograms were normal. Nothing has been found except the hypertension and the intermittent albumin in the urine. The family history on both sides is negative for hypertension. In the past history of the patient there is one factor which may have a bearing on the hypertension. When about 6 years old she drank an ounce or so of kerosene. Could the kerosene have damaged her kidneys at the time? Are there any studies on kerosene taken orally damaging the kidneys?

M D, South Carolina

ANSWER—Oral poisoning by kerosene usually is considered in conjunction with such other petroleum fractions as naphtha, gasoline and mineral spirits. Clinical manifestations are similar but not necessarily identical. The mortality from gasoline is much higher than from kerosene. At times the ingestion of sizable amounts (exact amounts frequently unknown) is followed by no untoward events. Conversely, smaller quantities have on occasion caused death. Early symptoms are chiefly related to the gastrointestinal tract, such as burning pain in the throat and stomach, vomiting, intestinal pain, diarrhea and great thirst, other effects are dyspnea, cyanosis, drowsiness, nephritis, cystitis and at times elevated temperature. Some survivors may exhibit prolonged significant sequelae. In the case mentioned, much depends on the extent of total damage soon after the kerosene ingestion. If extensive, it is permissible to assume that kidney damage probably existed at that time. Many reports have been made on this subject, not all of which mention nephritis.

INCONTINENCE AFTER TEAR OF SPHINCTER FROM
CHILDBIRTH

To the Editor—In the case of some fistulas in ano it is said, and I have known this to be true, that the sphincter can be cut at any place in its circumference and at any angle and healing will occur without incontinence provided the area is not packed longer than twenty-four hours. Why will incontinence always occur after a tear through the sphincter following childbirth?

Major, M. C., A. U. S.

ANSWER—Incontinence follows a tear through the sphincter following childbirth because the perineal body is torn into which the sphincter muscles attach themselves anteriorly. This allows the sphincters to open when they contract rather than to make a closure. This results in incontinence.

CLEFT PALATE AT SIXTEEN

To the Editor—A patient aged 16 has a cleft palate. The posterior two thirds of the hard palate has an aperture about 1.5 cm wide. What would be the prognosis if corrective surgery should be attempted at this time and what improvement in speech defect might be expected?

A. A. Skemp, M.D., La Crosse, Wis.

ANSWER—The development of the musculature of the upper part of the pharynx will largely determine the result of a simple operation of closing the palate. In all probability the palate can be closed unless much tissue has been lost from previous operations.

Where the muscle action mentioned is deficient, a much better speech result can be obtained by special speech training or, if necessary, by lengthening the palate by further surgery. This had best be done by some one familiar with this work.

Some idea of the muscle activity can usually be gained by depressing the tongue and stimulating the posterior wall of the upper pharynx by pressing on it with a cotton applicator and observing the contraction at the junction of the nasopharynx with the oropharynx.

BLISTER BUGS AND CHIGGERS

To the Editor—In the August 7 issue of *The Journal*, page 1054, a lieutenant from the Medical Corps, Army of the United States, describes a vesicular eruption occurring presumably after the bite of an insect. In addition he asks whether there is any insect called a blister bug. In the reply the statement is made that no blister bug is known. In this region, bites are not infrequent from a beetle called locally a "blister beetle." These are of the family Meloidae, species *Cantharis vesicatoria*. More commonly these beetles are spoken of as a Spanish fly. The active irritant from this insect is cantharidin, which is a well known vesicant. The bite from this beetle is painful and results in an erythema and a cluster of vesicles. It is not impossible that the lesion described by the lieutenant may result from a bite by this beetle. As far as I know there is no specific treatment.

Ramsdell Gurney, Captain, M. C., A. U. S.

To the Editor—Some one asks if there is any insect called a "blister bug." Your editor replies "No blister bug is known, possibly that name might be applied to the chigger." This is utter nonsense, blister beetles are very common in this section. If my brother Will were here he would tell me the Latin name for them, they belong to the family Cantharidae, which ought to strike up a few associations in the mind of your esteemed dermatologic editor. They are a narrow, elongated beetle with a red thorax. Both the bite and the crushing of the insect against the skin cause pain, vesicle formation and itching. My sister has a half dozen vesicles on her leg at the present moment and my wife has one on her neck. Every farmer knows them, every rural doctor knows them, and I have a suspicion that one or two doctors in Chicago know them.

Karl Menninger, M.D., Topeka

To the Editor—There are two organisms locally known or included under the name of "chigger"—originally spelled jigger. One is the larva of an arachnid which goes under the name of *Leptus autumnalis* or harvest mite, as you state. This is a relatively unimportant organism which is active in the fall of the year chiefly, hence the name harvest mite. The other one is an insect belonging to the fleas of the subfamily Sarcopsyllinae. It is a minute insect and is seldom seen even by its victims. It is only about 1/24 inch long. The female when pregnant buries herself in the skin. The active period of the insect is about sixty days beginning the latter part of June. It is so bad in this section of the country during July that some men give up their golf during the chigger season. It is a real problem both for the reason of the great discomfort it causes and from the fact that the bites sometimes become infected and lead to abscesses. The chigger gets on its victim from the grass, so that the application of any preventive must be as high as any grass which one is likely to come in contact with and must be applied to all parts of the body which will come in contact with grass. For example, picnickers should apply the preventive up to the waist if they are going to sit on the ground. The chigger attacks any part of the body it reaches. The feet are frequent sites of attack. The common preventives are kerosene and sulfur, which must be applied to the feet and legs as high as the grass, or higher.

I have experimented with several "chigger skoots." I found that an application of Kresol Dip ten drops to a cup of water, rubbed on my legs up to my knees would allow me freedom from chiggers even when hunting my ball in the rough. One difficulty with sulfur dusted in the hose or on the legs is that if one perspires freely, as one does on the golf course during the chigger season, the perspiration seems to wash off the sulfur. I have found that sublimed sulfur mixed with vanishing cream is a much better and surer preventive. With any preventive the application must be as high as the grass with which one comes in contact. The chigger bite is at first scarcely discernible and its presence is manifest by a mild itching, which becomes intense on scratching. The scratching seems to augment the edema, and before one realizes it one has denuded an area from 1 to 2 millimeters in diameter. The itching continues for about a week, especially when parts of the body covered by clothing are exposed to the air. Continued scratching enlarges the denuded areas until they are usually 5 mm in diameter or larger. The legs of country children are frequently datted with these scabs during the chigger season.

The other statement in your answer that needs revision is in regard to the blister bug. You know that it is a common practice to call every insect that flies a fly, and every insect that crawls a bug. There is an insect, a beetle, that has been known since medieval times as the "blister beetle." It is also known as the Spanish fly. Of course, in the entomologic sense it is not a bug since this name is reserved for members of the Heteroptera, while beetles belong to the Coleoptera, therefore your answer is technically correct. But as said this beetle has been called the blister beetle, or blister bug, since medieval times. It gets its name from the fact that if the insect is dried and the powder made into a poultice and applied to the skin it will cause erythema or even vesiculation. It was once a valued item in the physician's armamentarium. It is reported that if this insect is mashed on the skin and the "juice" is not removed a "blister" will form in the site.

Professor of Pathology, University of Oklahoma

LEFT HANDEDNESS

To the Editor—In *The Journal*, June 26, 1943, page 642, an inquiry and an answer appeared concerning lefthandedness. I disagree slightly with the advice given. Parents should not encourage the child to use the right hand in eating but permit her to work out her own salvation. She may find social embarrassment in left handed writing or left footed dancing. The persons answering the question properly stated that "all effects may follow if a predominantly left handed child is forced to use the right hand." If a child is 3 years old it should not be difficult to determine the hand. There may be hand that she voluntarily uses for eating and writing. There may be advantages in determining whether she has right or left eye dominance. In determining her future education. At the present time however she should be permitted to have the complete emergence of her structural preference.

Ira S. Wile, M.D., New York

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE
DEPARTMENT, MAY-AUGUST 1943

Titles have been listed or abstracts made of important articles in the following journals in the Current Literature Department of THE JOURNAL during the past four months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Three journals may be borrowed at a time. No journals are available prior to 1933. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "OS," Organization Section; "ab," abstracts; the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: Book Notices, "Deaths," "Medical Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 1332

A

A. P. C. See Respiratory System Infection
